66½ lighter weight per Square than Bangor  
Slates.  
30 per cent. greater mechanical and tensile  
strength.  
Non-Conducting.    Impervious to sun-  
Non-Combustible.    heat, frost and rain.

### SPECIALITY:

"ETERNIT" Terra-Cotta Tiles which  
neither break nor crumble, and at half the  
cost of Red Clay Tiles and double the  
strength. Stronger than any other Asbestos  
Slate.

## "ETERNIT" (Asbestos-Cement) SHEET FOR WALLS AND CEILINGS.

Fireproof; easily and rapidly fixed with carpenters' tools. Does not rot or shrink, and supersedes lath,  
plaster and matching. Size 8 ft. by 4 ft.—4 ft. by 4 ft. by ½ in. thick and upwards. Manufactured  
under the British Patent Rights.

# "HANDBOOK OF THE BRITISH COLONIAL EMPIRE."

BY

**W. H. MERCER, C.M.G.,**

*One of the Crown Agents for the Colonies ;*

AND

**A. J. HARDING,**

*Of the Colonial Office.*

---

"Whilst the 'Colonial Office List' is issued mainly for the use of the official world, the present volume is intended primarily for educational purposes and for the use of those desiring succinct and reliable information regarding the history, trade, government, and commercial development of the various outlying portions of the Empire. A large amount of useful information upon those subjects has been gathered together by the Authors, who, owing to their official positions in the Colonial Civil Service, have had exceptional opportunities for obtaining the latest and most authentic details regarding the present administrative and commercial state of all parts of the Empire. The book is well suited for educational purposes, and might with advantage be introduced not only into the schools of the United Kingdom, but adopted by Colonial educational institutions in order that students in any single portion of the Empire may know something of the history, character, and condition of all its widely scattered parts."

*Journal of the Royal Colonial Institute.*

\* \* \* \* \*

"The book is intended for educational purposes and is so attractively written, and contains such a fund of information, that it cannot fail to become popular."

*Education.*

EDITORIAL NOTES.

THE Imperial Naval Conference, which is to be held in London in the month of July, is the outcome of a resolution passed by the Imperial Conference of 1907 that subsidiary conferences should be held from time to time to consider special subjects when occasion arose between the dates fixed for the periodic meetings of the general conference. On this occasion special interest attaches to it in connection with the discussion as to the strength of the fleet which followed upon the introduction of the Navy Estimates, and the remarkable movement in favour of effective naval co-operation which has arisen in the self-governing dominions. New Zealand's prompt and munificent offer of a "Dreadnought" to the Imperial Government, coupled with a further promise of a second vessel, if required, and the similar action since taken by the Commonwealth Government, have furnished a striking appeal to the imagination, and have served as an indication of the almost indefinite elasticity of the resources which the British Empire has in ultimate reserve for defence purposes. But it is evident that a general and coherent scheme of co-operation should be adopted if there is to be a proper economy of effort, and the

decision of the Government to invite discussion of such a scheme at a moment when the general readiness to co-operate is manifest has been well received.

---

The presence in England of the delegates to the Naval Conference, and also of the delegation which is expected from South Africa in connection with the passing through Parliament of the scheme of Closer Union, will result in an assembly of Statesmen hardly less representative of the Empire than the last Imperial Conference itself. Meanwhile, the Imperial Press Conference has supplied a precedent for a highly interesting Imperial gathering of an unofficial character, and the notable speech of welcome delivered to the delegates by Lord Rosebery may almost be said already to have become historic. A noticeable feature of the proceedings has been the concentration of interest on the subject of Imperial defence, and the almost complete unanimity of sentiment among the delegates on this subject. Lord Rosebery's speech in fact set the tone which ran through the whole of the subsequent discussions.

---

The progress of the movement towards South African Union has been somewhat more eventful, and less uniformly smooth, during the past few months. The scheme formed by the Convention was subjected to searching criticism in the Parliaments of the Cape and Natal, and at one time there was a fear that the amendment introduced by those two bodies might result in a deadlock when the Convention re-assembled for its final meeting at Bloemfontein. The scheme was in its very essence a compromise between conflicting interests and too great insistence by any section upon its own favourite policy would inevitably have led to disaster. But the delegates at Bloemfontein once more showed a remarkable practical statesmanship, and it was found possible to effect a compromise acceptable to all parties. Various minor concessions were made to Natal, while the Cape secured the abandonment of the principle of proportional representation in the elections for the Assembly. This last alteration will be regretted by many students of political institutions. But it must be remembered that, while the English observer may find it convenient that our distant dominions should serve as "laboratories for political experiments," the dominions themselves may reasonably hesitate before adopting a system which, however interesting and theoretically admirable it may be, has been little tested in practice. From the party point of view, it would seem probable that one party will gain in the town and the other in the country, by the change which has been made. There can be no doubt that South Africa is in some ways a peculiarly suitable field for a system of proportional representation, because without such a

system there will remain in many districts a permanent minority which can never hope to be represented in Parliament.

---

The Convention as redrafted in Bloemfontein was approved unanimously by the Parliaments of the Transvaal and Orange River Colony, and with the minimum of criticism by that of the Cape. But in accordance with pledges given some time since, it became necessary to submit it in Natal to the more perilous ordeal of a popular referendum. The results of such an appeal to the whole population are notoriously uncertain all the world over, and in the case of Natal the opposition which had been aroused by the agreement between the Transvaal and Mozambique (in spite of the fact that the Natal Ministry had been kept fully informed of the course of the negotiations), and the comparative isolation of the Colony from the inter-Colonial connections which are so strong in the case of its three neighbours, led many friends of Union to fear a defeat. Both sides pursued an active campaign, and popular excitement ran very high. But as the date of the referendum approached, it became increasingly clear that the larger issues would outweigh all smaller considerations, and that no local or sectional interests would be allowed to wreck the scheme on which so much labour had been expended. Even if Natal had hung back, it was generally recognized that a union of the other Colonies would be effected, and that the accession of Natal to such a union would only have been postponed. Her position would probably have been much like that of Western Australia at the time when the Commonwealth Bill came before the Imperial Parliament. But the actual result of the referendum showed a majority of 7,420 in favour of Union, and the completion of the whole scheme, so far as the self-governing Colonies of South Africa are concerned, is now certain. The progress of the Bill through the Imperial Parliament will be watched with interest, but it is obvious that it stands in no danger of rejection, or even of substantial alteration.

---

Mr. Fisher's Cabinet in the Commonwealth has met with the same fate which overtook the previous Labour Ministry over which Mr. Watson presided, and its lease of power has been too short for it to have left any marked impress either on legislation or administration. It is far from easy to forecast the political future in the Commonwealth. The new Cabinet is composed of such diverse elements that its legislative programme must be a matter of the utmost uncertainty, and to many observers there have seemed to be far more points of agreement between Mr. Deakin and Mr. Fisher than between Mr. Deakin and his new associates. With the existing position of parties in Australia, it is hardly possible for any Government to rely solely upon a single homogeneous party for

support, and instability is the inevitable result of the ever-present possibility of a change in party combinations. It is possible that the election of next year may provide an absolute majority for one party, and unless this occurs it is difficult to see how frequent Cabinet changes are to be avoided. The situation is unfortunate ; for the Commonwealth Government has much difficult work ahead of it. Both Mr. Deakin and Mr. Fisher have given expression to their sense of a need for constitutional amendments to enlarge the powers of the Commonwealth, and the marked tendency shown by the High Court to put a narrow interpretation on those powers—a tendency to which Mr. Wise refers in a volume which we review elsewhere—is bound to give a fresh impulse to the policy so outlined. The death of Mr. Price, the late Premier of South Australia, has removed one of the most notable figures from the sphere of State politics, and his successor would seem to have before him a task hardly less difficult than Mr. Deakin's.

---

It was found impossible to remove the political deadlock in Newfoundland without recourse to a second general election, but the result of this has been to give a substantial majority to Sir Edward Morris, and one of the most curious political situations which has ever existed in any British Colony is thus brought to a close.

---

The Canadian Labour Gazette for April contains a favourable account of the immigration prospects for the current year. "Indications are that the number of immigrants coming into Canada this year will be considerably larger than in 1908. Some increase in arrivals by ocean ports has already been shown over last year. The influx of settlers into Western Canada from the United States has been on a very heavy scale for several weeks past, most of the settlers having purchased land, and bringing in their stock and other effects. The opening of the pre-emption areas, making it possible for a settler to acquire 320 acres, instead of 160 as formerly, has also stimulated the movement." In spite of this, the Board of Trade figures of emigration from the United Kingdom give the impression that the decline in emigration to Canada is continuing. During the first three months of the year 12,916 persons of British origin left the United Kingdom for British North America, as compared with 15,774 in the same period of 1908. On the other hand there was a substantial increase—from 5,432 to 8,483—in the number of departures for Australia and New Zealand. This change in the direction of the stream of emigration is to be attributed partly to economic causes, but also partly to a change in the policy of the governments of the dominions concerned. Canada is becoming more inclined to be critical, and to pick and choose among would-be emigrants. Australia is becoming increasingly alive to the need of

new settlers if the potentialities of the country are to be fully developed.

---

The New Zealand Government have made for their own purposes an examination of a number of the ports of the United Kingdom, and the results have been published in a parliamentary paper. Bristol, Cardiff, Liverpool, Manchester, Glasgow and London were visited, and details are given at length of the port accommodation and facilities, and the convenience of situation for distribution of goods. Manchester and Bristol are singled out for special praise as having made "most ample and satisfactory provision for the handling and storage of frozen meat and other perishable produce," and neither Liverpool nor London come near them in this respect. The chief difficulty at present in the New Zealand trade is the irregularity of the steamship sailings and uncertainty of the charges. The buyer at this end wants a system of regular supplies, especially in the case of perishable produce, and if the sailings from the Colony are irregular, the supply is too abundant for his purposes at one time and deficient at another. Uncertain freights naturally discourage business, and it is interesting to note that it is the uncertainty that causes the trouble, rather than the charges, because "as New Zealand products have to compete in the open market with those of other countries, it is apparent that the costs of transit and handling must fall upon producers." The case supports the views of those merchants who think that it is worth while to pay an extra price to the steamships to secure fixed rates and sailings. The Report advocates a Government subsidy, which amounts to the same thing. Possibly the object might be achieved by combination between the producer and buyer directed to secure regular supplies at fixed freights.

---

The importance of securing provision for cold storage is strongly brought out by the information given by Mr. J. A. Ruddick, the Canadian Dairying and Cold Storage Commissioner to the Select Standing Committee on Agriculture and Colonisation. The Canadian authorities have dealt with the matter with singular thoroughness. In every way production on first class lines is stimulated: prizes are given for milk yields; bonuses for cold storage creameries; grants for iced car services; and arrangements have been made with various steamship lines for the carriage of fruit in cooled chambers. All this entails a constant watch on the quality of produce, and it is only natural that good results should come from this machinery of inspection, advice, and co-operation. The change really has been marvellous, and forms a striking testimony to the power of government organisation. It should not

be overlooked that Great Britain itself is largely interested in these improvements. They mean a bigger and better supply of the things produced for its population.

---

The National Memorial Tower which is being erected at Quebec will commemorate the epoch-making battle and the beginning of constitutional government a century and a half ago. The first parliamentary assembly in Canada met at Halifax in 1758: in 1759 the struggle on the Plains of Abraham took place. The Tower will be a historic landmark typifying the union of two races and the spirit of British institutions. Halifax has a similar undertaking, and Canada has good reason to be proud of these and many other municipal expressions of a patriotic interest in her past.

---

The long delayed report of the Royal Commission on Shipping Rings has at last been issued as a Blue Book. It is a voluminous document on a somewhat intricate subject, and space will not permit of a lengthy review in the present number. We shall hope to deal more fully with the subject in our next issue. Briefly, it may be stated that in their conclusions and recommendations the Commissioners are not unanimous. The majority propose as a remedy for the abuses of the Conference System:—

“The recognition and encouragement of associations of merchants and shippers in given trades, who by combination would be able to present a united front to the Conference when any controversy arose. That such associations should be registered by the Board of Trade, and that in cases of dispute the Board of Trade should be empowered to appoint an Arbitrator or endeavour to obtain a settlement by conciliation.”

The minority submit that the Conference System has established a monopoly of the chief ocean routes; has raised and kept up rates; has been injurious to “tramps” or outside steamers; and has caused, in the case of South Africa, diversion of British trade. They recommend Board of Trade supervision, but suggest wider powers for the Board, and an annual return to Parliament of all Shipping Conferences, Conference agreements, extensions, or changes, if any, in the areas of Conferences, their amalgamation, &c., so that Parliament may be made acquainted and kept in touch with the working and development of the Conference System.

---

One of the first subjects which will call for the attention of the South African Parliament will be the Customs tariff, and here topographical differences will make themselves felt to an unusual extent. The protective duties which are at present levied at the coast operate to the benefit of industries at or near the coast, and here living is

cheaper, wages lower, and skilled labour more abundant than in the interior. There is little chance therefore that in the interior industries can be established to any great extent able to compete with those on the coast, and the interests of the inhabitants therefore favour lower duties so far as these are protective. The annual report of the Johannesburg Chamber of Commerce lays stress on the handicap imposed on the Transvaal by the taxes on food and other articles of general consumption, and no doubt efforts will be made to get them reduced. The agricultural interests of South Africa are quite capable of responding to increased competition, and we expect that future developments will be on the lines of cheaper living, due both to lower duties and improved local production, and consequently greater commercial enterprise.

---

A large part of the difficulty in South Africa is owing to the fact that the coast colonies have been tempted by the industrial activity in the Transvaal to make money out of the goods that have passed through their territory for that destination, instead of relying on their own resources. The Transvaal has dominated the commercial situation, and a large expenditure has been incurred on railways to enable the people on the coast to reap a harvest as forwarding agents and toll-gatherers. Unfortunately for these lines the route from Delagoa Bay is shorter and cheaper, and though out of loyalty to the sister colonies the Transvaal has kept up the rate on this route to the same amount as that on the others, it is obvious that an arrangement under which the Transvaal deliberately sacrificed an important advantage was of a highly artificial character and by no means sure to prove permanent. To have thrown over Cape Colony and Natal in this matter would have been to inflict a terrible blow, and the only way in which the Transvaal could save them and at the same time relieve herself from burdensome rates was to unite South Africa.

---

At the annual meeting of the Witwatersrand Native Labour Association the Chairman, Mr. F. Perry, stated that there were 47,766 more native labourers employed by members of the Association at the end than at the beginning of last year, and that allowing for the repatriated Chinese there was a net gain of 24,373, to which may be added 11,515 for the first quarter of the present year. A large part of this increase on the Rand is no doubt directly or indirectly attributable to the limitation of De Beers operations, but it is clear that a much larger number of natives from Cape Colony now come to the mines; five years ago it was 14,000, last year it was 40,000, and this result shows what can be done by effort and organisation.

We desire to offer our congratulations and best wishes to a new contemporary, *The Northern Rhodesian Journal*, Vol. I., No. 1, of which has made its appearance at Fort Jameson under the editorship of the Rev. W. J. Bell. The standpoint of the paper is happily expressed in the following extract from the "Editorial":—

"As to politics, we are Conservative-Home-Rule-Radicals.

"CONSERVATIVE, because we voice a Farming Community.

"HOME-RULE, because we are British citizens, and will therefore insist in deciding how we are to be ruled.

"RADICAL, because we are colonists and do not wish to make our colony just a replica of the Home land with all its conventionalities."

---

The fourth annual report of the British Cotton Growing Association states that although the results of 1908 are not as satisfactory as could be wished, the Council are not in any way discouraged, especially as recent reports from West Africa and Uganda are most promising. Depression in trade and the Lancashire cotton dispute caused low prices, and this condition of things is of course unfavourable to the enterprise of the association, which was brought into being by high prices. The demand, however, is sure to revive, and to give increased encouragement to colonial-grown cotton. The total production of cotton under the auspices of the association amounted to 23,000 bales, of a value of £360,000, and a heavy correspondence is conducted on matters connected with the industry. There was a deficit of £31,647 on the year's working, due mostly to the partial failure from drought of the West African crop. Much better results are expected from 1908-9.

---

The last report on Papua is, like its predecessors, specially interesting as embodying the results of Australian administration of a people of very primitive type. The inhabitants are generally, as absolutely uncivilized races usually are, exceedingly nervous and suspicious, and this is not to be wondered at when it is considered that sudden raids and treacherous murders were regular occurrences. Evidently the habit of fighting is still strong. As an instance of this, the Administrator tells a curious story of how he tried two men for throwing spears at the police; they pleaded guilty, and he explained to them through interpreters that they must never do it again. Thereupon they asked that they might be hanged, and when asked their reason said that their only pleasure in life was throwing spears at the police, and if this was denied them they did not wish to live. The Administrator truly remarks that it is difficult to put oneself in the position of such a person mentally, and more difficult still to imagine what he will be like when he is civilized. Probably it was a case of child-like petulance, and there are signs that when

greater security to life is guaranteed these natives will settle down to agricultural pursuits.

---

The official report states that the language of the Papuans cannot be better described than as resembling the snarling of dogs interspersed with hiccoughs. This reminds us that to the ancient Greeks the speech of foreigners seemed like the twittering of birds, and we should be glad to know what the Papuans themselves think of the English tongue. After this unappreciative description of their language, we are not surprised at being told that many of them are a murderous lot, and repulsive in appearance. Yet "experience has shown that this type of native may be brought to a state of comparative civilization without any very great difficulty by the exercise of tact and patience. As, for instance, was the case with the Red Creek natives in the Northern Division, mentioned in the last annual report, who from apparently tameless savages have now developed into a race of market gardeners and carriers."

---

The revenue of the Leeward Islands in 1907-8 was the largest ever collected, and the financial results of the first nine months of 1908-9 showed a further increase of revenue. The marked improvement is due in the case of Antigua to the encouragement given to sugar production by the two central factories and to the cultivation of cotton. Gunthorpe's factory returns 12 to 15 per cent. on capital, and this success should lead to the establishment of factories in other places; the benefit to growers is of course considerable, and the case is a good instance of the improvement which can be effected in such an industry by Government action, aiming at combination and co-operation. On the other hand, some planters have lost money on cotton growing, and the export in 1909 is not likely to equal that in 1908: the moral is that the industry is only remunerative on land which gives a good yield.

---

Mr. Carnegie has generously given £2,000 to Seychelles for the erection of a public library, on condition that a free site should be provided without creating a burden on the revenue of the colony, and that £100 a year revenue should be guaranteed by the Government. These conditions have been complied with. Mr. Carnegie had previously shown similar generosity to British Guiana and to Barbados.

---

The Bill introduced by the President of the Board of Trade to abolish sweating and establish a minimum wage in scheduled trades follows the example set by Victoria in 1896. The first trades selected in Victoria were, as here, those in which sweating is most marked, and were similar in character to those now scheduled in the Bill.

The first Act of the colony was passed for four years and against strong opposition ; but when it was about to expire, some of those who had most energetically opposed it voted for its renewal, largely because they benefited themselves by the suppression of the unconscientious employer. The Act is now permanent and is generally regarded as very beneficial. No doubt the task of levelling up wages in these poor industries is more difficult in the United Kingdom than in a colony which has a protective tariff, as any increase in cost may drive the trade abroad, but it seems well worth while to run some risk of this rather than to tolerate a condition of things which makes decent life impossible.

Even apart from this consideration, we think that the attack upon sweating will be justified economically. Sweated industries mean shoddy goods, and are bad in the long run both to the consumer and to the better-class manufacturer. Competition which is allowed to go on with no restrictions inevitably results in frantic efforts to cheapen production, and the result is seen in supplies in which the manufacturer reduces the quality in a more or less underhand manner. The deficiency can only be discovered by severe tests, which take time and cost money, and the maker, in not a few cases, relies upon the expectation that his goods will be accepted if they seem all right, and on the knowledge that their rejection will probably cause a serious loss of time. The competition of these people naturally tends to lower the standard of more honest manufacturers. The chief essential for good work is good workmanship, and this, more than coal or iron, or anything else, is the great asset of this country. Good workmanship, however, can only be secured by fair wages, and a decent minimum is in the interests of everybody, not excluding the sweater himself.

---

Thanks to the generosity of a Parsee resident, Mr. H. N. Mody, there is every prospect that Hong Kong will soon be in possession of a University. Mr. Mody's original offer was to provide a sum of \$150,000 for building and a further sum of \$30,000 for endowment. He has since increased his offer to the sum of \$300,000, provided that the sum of \$110,000 required for endowment is raised by the end of the current year. Sir Frederic Lugard has interested himself actively in the scheme and has obtained the Secretary of State's approval of the provision of a suitable site by the Colonial Government. The scope of the University will include a Faculty of Medicine, a Faculty of Applied Science (Engineering, &c.), and later a Degree of Arts, as well as Chinese Literature and Classics. The China Association has issued an appeal in support of the scheme, from which we extract the following passage :—

“The University would enhance the standing of the colony, and would prove of inestimable advantage to Chinese, whether

resident in the Empire itself, in Hong Kong, in the Straits Settlements, or in Indo-China, by providing facilities for the acquisition of Western learning practically at their doors, while it is hoped that the training would dispose students to remember sympathetically in after-life the associations and teachers connected with their education gained in a British Colony."

We understand that considerable financial support has already been obtained in this country.

---

The despatch of an American mission to Liberia is a striking mark of the traditional interest taken by the Republic in the fortunes of this community. It cannot be said that Liberia has done much to keep pace with the energetic progress of its neighbours; and there are inevitably occasions when the absence of proper administrative arrangements, according to our ideas, creates awkward situations. It would be unfortunate if any serious crisis arose out of these embarrassments, and it would be a clear advantage to us if the American mission succeed in securing effective arrangements for good government. The difficulty is that the Liberians who possess American associations have not succeeded in making their authority over the aboriginal tribes effective.

The United States Government have now realised that all is not plain sailing when liberal constitutions have been given to native communities. The Assembly of Puerto Rico has (as was bound to happen) refused to vote supplies, and President Taft has observed that "we have gone somewhat too fast in the extension of political power to them for their own good," and has recommended Congress to amend the constitution act. The same result has come to pass in the Philippines and Hawaii.

### COLONIAL LOAN ISSUES.

IN the piping days when money is cheap in the City, the colonies, great and small, descend upon the fold with the firm intention of getting their share of the good things going. When money in this quarter is dear, a situation indicated sufficiently by the Bank rate, then applications are put off for a better day. The future course of money is always a problem which defies calculation, and, though there are experts who discourse on prospective movements, it may be noticed that their prophecies are very short-dated; the City in fact is little interested in any anticipations, however apparently intelligent, which go beyond the next settling day. Still there is a sort of rough average about the price of money which is enough to settle the question whether money is plentiful enough to tempt borrowers to come on the market, or so scarce as to deter them. Of course when the supply of money is referred to in this way, it is only for certain purposes. The world's capital at large does not go up and down in marked fluctuations, but the amount available for borrowers does. The point of view is strictly that of the Stock Exchange and the financial newspaper. If industries are remunerative here and elsewhere—and for the purposes of the money market it is obviously necessary to take a world-wide view—money is made and saved, and becomes for the time being surplus, and it is therefore available for investment. The time when such money is most abundant is not the moment of the greatest production and exchange, but shortly after it. At a time of active business more money is put into established industries, but there comes a period when the local requirements are satisfied, and then the chance arrives for investments further afield. On the other hand if the borrower delays to seize the psychological moment, a further diminution of industry brings about reduced profits and a shaking of the feeling of confidence, and therefrom the hoarding of money, or, what practically comes to the same thing, the lending of it on short notice. Then it is necessary to

make an effort to attract more capital; up goes the Bank rate, and the opportunity of the borrower or exploiter is gone. The movement is of a cyclic character; business operations cannot be so adjusted that supply and demand are always equally matched. The supplier as a rule goes on producing in ignorance of the fact that his customers have had nearly enough, and the latter give no notice of their position. They are in fact at arm's length, and go on till they are advised by some calamity that the old expectations require revision. Some day, when the millennium is nearly due, there may be a machinery for regulating these things, but in the meantime it is clear that there will be recurrent ups and downs in the financial world.

If a borrowing State has the misfortune to require money when the rate is high, the most economical course is to borrow for the time being against the unissued scrip and to postpone the flotation of the loan itself for a better opportunity. It has then to pay the high rate of interest, but only on such amounts as are absolutely required from month to month to keep the works going; whereas if the loan were issued, interest would be payable on the whole sum, though that would not be required for perhaps two or three years, and the high rate of interest would be payable for the whole currency of the loan, which is usually about fifty years. There is of course always an element of speculation in the matter; the Bank rate may go still higher and persist in this objectionable attitude till the loan must perforce be issued. Having regard, however, to the general periodicity of financial movements, the balance of advantage is in favour of waiting for a reasonable opportunity, and meeting the requirements meanwhile by temporary accommodation.

There is another reason for putting off the issue of a loan till a substantial part of the money has been spent. A colony always pays more interest on a loan than it does on advances. The reason is that money lent at call or on short notice carries interest at a rate considerably lower than money which is locked up. Therefore, putting aside all speculation, it is advantageous to borrow temporarily, and it is often possible to continue to do so until the works for which the loan is required are nearly complete.

It is the practice now-a-days on the issue of colonial loans and others of a like kind to get them underwritten. The underwriters, in consideration of a commission, which is usually 1 per cent., undertake to take so much of the loan as is not subscribed for by the public. Governments would, of course, not sacrifice 1 per cent. if they could get the money without employing underwriters, but experience has shown that on the whole they gain by doing so. Only a very small part of a loan is applied for by the real public at the time of issue. The ordinary investor buys stocks and shares at a moment when he has money available, which is not often; it is the

professional who examines the morning newspaper and makes use of the few hours, which are often all that is allowed, to come to a decision and send in his application. If the issue is readily taken up so that the price is likely to go to a premium, the list must be closed early, as otherwise on the news getting about a vast number of applications would be sent in with the object of getting advantage of the premium, and this would be unfair to the genuine applicants. The result is that the success depends practically on the view which the market takes of the deal, and this is largely a matter of the influence of the financial houses interested. The underwriters hope to bring the price to a premium, and can then unload more or less promptly at a profit well worth having ; in some cases they have to hold for a long period, perhaps a year or two, before they get rid of their holdings. In the latter case there are no pickings for the Stock Exchange, and the issue is denounced by some of the financial papers as a failure. This means that the colony has got the money cheaper than the Stock Exchange thinks right, but it is obviously undesirable, in view of future issues, that a colony should get a bad name or imperil the prospects of the others, and the best result on a general view is that the issue should go off well and rise for the time being to a fractional premium. If, however, the premium becomes a substantial one, the presumption is that the borrower has let the loan go too cheap. Not much should be made of the fact that a loan is subscribed several times over. The City is eager enough to take up a safe thing, and if it is bruited about that a loan is going off like hot cakes the "stags" rush in and apply for enormous amounts which they could not take up, well knowing that their allotments, if they get any, will be a very inconsiderable proportion of what they apply for. The L.C.C. loan recently issued was subscribed for 60 or 70 times over.

The real bargain is thus made with the underwriters. The agents for the borrowing colony have to ascertain the prospects and, so to speak, feel the pulse of the City, and after many inquiries and consultations the terms of issue are agreed upon. The colony, so far as the particular issue is concerned, is not interested by anything that happens afterwards ; it has got the money at an agreed price, and the only object of the public flotation is to pass the stock on to the private investor and to make a market in it. The professional character of the transaction is the reason why loans are frequently offered in the shape of bonds convertible after a few years into inscribed stock. Bonds are much more convenient than inscribed stock to financial houses. They are payable to bearer and pass readily from hand to hand as first-class securities for advances. They cannot depreciate in value to any material extent, because they must be redeemed at par at maturity, which is commonly after four years' currency. Thus they are attractive to the City, and

borrowers make use of the fact to facilitate the floating of the loan on good terms. The private investor, on the other hand, finds it more convenient to inscribe, for then his title is secure and does not depend on a piece of paper which can be lost or stolen; furthermore, trustees cannot hold these bonds and must inscribe. The process of conversion therefore sets in as the loan passes into the possession of the public.

It is essential to successful borrowing that there should be no alarm from foreign politics. This is the principal danger in the eyes of the City; not domestic politics, nor even budgets, greatly disturb Stock Exchange movements, but the breath of a suspicion of foreign complications instantly sends prices down and rates up. The average investor is not much affected by sudden panics; he does not dump his stock down, but holds on grimly; what he has to fear is a gradual undermining of values. But financial houses, living in a sense from hand to mouth and dependent on the varying price of money, are extremely sensitive to such influences. That Government deserves best of the city which keeps clear of foreign complications.

Everyone is remarking the great number and size of colonial and municipal loans which are being issued, and the phenomenon has a very important significance apart from its financial aspect. It means that public bodies are invading more and more the fields of private enterprise. All political parties are from time to time being involved in undertakings which can truthfully be described as collectivist and anti-individualistic, so much so that the old *laissez-faire* doctrine is out of sight, the theories of Spencer and Mill obsolete, and the whole Empire, according to timid observers, plunged into a maelstrom of socialistic schemes. This general movement is due not so much to academic reasoning, as to the multiplication of tempting opportunities, and one main reason why they are tempting is that public bodies can get money more cheaply than any one else. Moreover, the money offered for such purposes seems to be steadily on the increase, and it may be of interest to point out why this is and must be the case. It is due to the operation in practice of the Trustee Act of 1893. It is not to any considerable extent the money of the living man which goes into Government stocks. The ordinary investor puts money into his own or his neighbour's business, or failing these opportunities into something which he expects will pay something more than  $3\frac{1}{2}$  per cent. To this end he studies some favourite financial organ which purports to give tips on every form of enterprise, and, though candour would often compel him to admit that he would be better off if he had never seen this kind of literature, the fact remains that he seldom patronises Government stocks till he has learnt by experience that there

is nothing like leather, and not often then. But the Act drives all trust moneys, with some very limited exceptions of certain railway bonds and the like, into public stocks, partly out of consideration for the welfare of the proverbial widow and orphan, and partly for the benefit of the State. A large part of the wealth of the country comes at some time or other into the hands of trustees and may remain there for a long period. It is, of course, open to testators and settlors to exclude the Act by giving trustees special powers of investment and restricting them to these, but a reference to the Act is simple, is on the safe side, and tends to become a common form. Even on the expiration of the trust much of the money remains undisturbed. The market is fairly active in dealings with the big stocks, but much of this is speculative and on the surface. Experience of the lesser known stocks shows that there is singularly little selling, and this indicates that beneficiaries are to a large extent content to leave things alone. The inevitable result is that a constantly increasing amount of wealth is being poured into such stocks, and this diversion from private to public undertakings has wide-reaching effects. The inclusion of Colonial Government stocks amongst those authorised for trustees was the result of an application put forward at the Colonial Conference of 1887, and founded on and justified by their security, but it is safe to say that the economic results were not foreseen.

There is much to be said for the Crown Colonies issues as a field for investment. The constitutional position is not generally understood, and it may be desirable to make some remarks in explanation of it. The Imperial Government gives no guarantee of these issues and is therefore not responsible for repayment or the meeting of the interest charges. Sometimes this has been explained officially, though in somewhat varying terms. But it is not by any means the whole of the matter. It is true that the Secretary of State for the Colonies undertakes no liability for the British tax-payer, but as regards the colony he controls the situation. It is only with his consent that the loan can be issued at all, and this consent is never given without minute examination of the intended purposes and the expectations built upon them. It is not too much to say that of all the loans raised on earth the Crown Colony loans are the most scrupulously devoted to public works of a directly industrial and reproductive character. We might add that they are the most economically and providently administered. From first to last the spending of the money is critically watched both in the colony and in Downing Street, and the result is that in the end there is a solid asset to show. The intervention of the Secretary of State in these matters is commonly enough followed by hostile criticism from some quarter, often both in the colony and at home.

It is unpleasant and invidious to put difficulties in the way of schemes which may be strongly demanded locally, but the duty is done and nothing is sanctioned until a reasonable case is clearly made out. Furthermore the Secretary of State is fully able to secure that the colony will make every effort to meet its liabilities. He could by a few strokes of the pen increase the estimated revenue or decrease the expenditure, and if there is any difficulty about carrying out his directions he can revoke the constitution and establish another one of a more compliant character. In return for these autocratic powers he gives the colonies the safeguards of sound finance, and whenever colonial publics are inclined to resent the slowness and caution with which the Colonial Office examine projects favoured by them, they should take into consideration the fact that, as the result of this control, the Crown Colonies enjoy a credit which is as good as and in some cases better than that of Australia.

Without such control it is quite certain that numerous costly enterprises would be undertaken which would eventually be mill-stones round the necks of the Colonies affected. There is a vast difference in such places between schemes which have to be paid for on the nail and those which can be provided for out of borrowed money. The white population in the hot countries is not there for life; it wants to make its pile as quickly as possible and get back home again, and it cannot therefore be as interested in the future welfare of the place as a population which is making it a permanent home. There is, therefore, a temptation to favour big schemes which will bring about a good deal of local work and spending of money, while the repayment is a long way off and will affect other people. On the other hand, any scheme of public improvement which it is proposed should be met from current revenue is often strongly criticised and opposed. The result is that it is generally easier to get a railway project through than a sanitary improvement.

High as the credit of the Crown Colonies is, considering their position and resources, it would be better except for the fact that the ordinary investor knows very little about them and mixes them up in his mind chiefly as homes of malaria and sleeping sickness. It cannot be expected that he will ever know much about the individual merits. The difficulty would be met by consolidating the debts of all the Crown Colonies, and this we are inclined to believe would not be so difficult as appears at first sight. It may, for instance, be urged that the rich colony should not be made liable for the poor colony, but as all expenditure is controlled by the Secretary of State the liabilities which the latter colony would be allowed to incur would not be out of proportion to its means. The question is worth consideration and will, we believe, become more important as

time goes on. The Crown Colonies are developing fast and entering the money market more and more ; a loan expenditure of several millions may be said to be in sight at this date. The consolidation into one stock would not only better the credit, but would create an active market at close prices. All Crown Colonies are already domiciled under one roof, and the consolidation, from a working point of view, could easily be carried out.

In any case the steady development and increasing importance of the Crown Colonies will tend to improve their credit, and the probability is that in comparison with other securities those of the Crown Colonies will appreciate in value.

## THE SETTLEMENT OF TRADE DISPUTES IN CANADA.

THE Canadian "Industrial Disputes Investigation Act" (generally known, after the name of its introducer, as the "Lemieux Act") has now been in operation for more than two years, and it is possible to form some opinion as to the degree of success which has attended it, and as to its general effect upon the relation of capital and labour in the Dominion. Such an enquiry is of especial interest at the present time, when machinery not unlike that established by the Lemieux Act has been set up at home in the case of the railways and in that of the shipbuilding trade. It is quite in accordance with British industrial traditions that this machinery should have been set up by purely voluntary action (assisted in one case, it is true, by the mediation of a Government department), and not by legislation. It is no less characteristic of Canadian, as distinct from Australasian methods, that the Lemieux Act should limit the functions of its Conciliation Boards to enquiry and report, and not confer upon them powers of final and authoritative decision. The Act, it will be remembered, provides for the appointment of a Board of Conciliation and Investigation, on the application of either party, when an industrial dispute is apprehended in services connected with "public utilities" or in mines; it forbids strikes or lock-outs pending an enquiry by such a board; and it provides for the publication by the board of a reasoned report and recommendations, which are not, however, in any way made binding upon the parties to the dispute. The hope of its framers was that the pressure of public opinion would suffice to bring about their acceptance.

The Canadian *Labour Gazette* for January contains an analysis of the operations conducted under the Act during 1908. Twenty-five disputes were reported upon by boards set up under the

Act, and in only one case—that of a dispute between the Canadian Pacific Railway Company and its mechanics—did a strike or lock-out occur. In this instance there was a majority report signed by two members of the board, and a minority report, signed by the remaining member. The findings of the majority were accepted by the Company, but not by the men. A strike followed and lasted for two months, when the men returned to work on the basis of the findings of the majority report. It is unfortunate that, in the number of men affected—8,000—this dispute should have been the most important dealt with under the Act. In the majority of the other cases, the disputes were settled in accordance with the recommendations of the Board of Conciliation. In a few cases, where there was a minority report, “it is believed that the circumstances brought to light during the investigation and the publicity given to such investigation were responsible for bringing about an improved situation, as a consequence of which the strike or lock-out originally threatened was averted.” At the close of the year four disputes were still under the consideration of boards, and it is interesting to notice that one of them was a dispute in the boot trade, referred for adjustment under the Act by joint consent of the parties, though the manufacture of boots does not fall within the definition of a public utility. In estimating the value of the results achieved under the Act, it must, of course, be remembered that the disputes settled were not comparable in importance to the great disputes which have occurred at home. The total number of men affected by twenty-four of the disputes—in the remaining case the number is not given—was 25,225.

The official report summarized above is nothing more than a bare record of facts and figures. But two more detailed studies of the actual working of the Act are also available. Dr. Victor S. Clark, who is a well-known authority on legislation affecting labour and industry, and the author of a valuable review of Australasian experiments in this field, was sent to Canada by the American Government to investigate the working of the Act, and his report (covering the period up to January 15th, 1908), was published in the issue for May, 1908, of the Bi-monthly Bulletin of the United States Bureau of Labour. Dr. Clark emphasises, at the outset, a fact of much importance. “The Canadian Act was put in force just before an industrial depression, on the verge of a period of unemployment and falling wages. Therefore in its natal year it was put to a severer test than have been the Australasian laws in the twelve years of their operation.” Allowing for this adverse circumstance, his verdict on the results of the Act is distinctly favourable. But he regards the reduction of the element of compulsion to a minimum as a necessary condition of its success. “Most boards have recognised that the spirit and intent of the law is conciliation, and that this can

## The Settlement of Trade Disputes in Canada. 21

best be secured by informal procedure, leaving penalty features of the law in the background, and depending on mutual understanding and goodwill even more than upon public opinion for a settlement. . . . Some of the least successful chairmen have been judges, though judges and lawyers are in other cases the first to grasp the distinction between conciliatory and judicial proceedings. A judge who organises a Board after the fashion of a court, sets it up on a dais, takes testimony according to legal rules of evidence, enforces legal technicalities, and checks up his witnesses by stenographic proceedings—so far as Canadian experience goes—leaves the parties at the end of their negotiations farther apart than at the beginning, and crystallizes tentative issues into insolvable difficulties. The most successful chairmen have been those who conducted their proceedings in the most informal manner, the members of the board, and the representatives presenting the two sides, sitting around a table, interviewing witnesses rather than examining them, and talking each other into an agreement." Upon this aspect of the functions of a Board of Investigation some interesting remarks were made to Dr. Clark by an eminent lawyer, a former judge of the Supreme Court of the Dominion: "The great difficulty," he said, "you would have in operating such a law in the United States is the tendency of your legislators, courts and lawyers, to sacrifice everything to formality. I fear this spirit would affect even non-legal tribunals like our Conciliation Boards. You would allow objections to evidence and such technical frivolities to defeat substantial justice. Your big labour leaders understand the matter much better, and I can see the force of their objection to statutory arbitration in the States. Formalities, differences as to admitting evidence, &c.—often in matters of detail and on minor points involving no general principle—breed a lot of ill-feeling and prevent conciliation." Dr. Clark's general conclusions are that the Act "has accomplished the main purpose for which it was intended, the prevention of strikes and lock-outs in public service industries"; that it is more applicable to American conditions than compulsory arbitration; that it has not affected adversely the industries to which it has been applied, or the workers in those industries; that employers and the general public, with very few exceptions, view it with favour; and that while working-class opinion is more divided, and it is impossible to say definitely whether, if a referendum were taken, the workers of Canada would accept or reject it, it is generally supported in the eastern provinces, and has been endorsed by the Trades and Labour Congress, the most influential labour body in Canada.

Even more valuable, as giving an inside view of the actual working of the Act, is an address delivered in December last at the

annual convention of the American Association for Labour Legislation at Atlantic City, New Jersey, by Professor Adam Shortt of Ottawa, who acted as chairman of no less than eleven boards under the Lemieux Act, and whose impartiality and good judgment have recently led the Dominion Government to select him as one of their first Civil Service Commissioners. Professor Shortt declares strongly against legislation for the compulsory settlement of trade differences, and he finds that even the compulsory submission of such differences to a board is difficult, if not impossible, to enforce. "Experience indicates that it is impossible, in a democratic community, to compel any considerable number of men to work under given terms of employment; nor, in spite of the hostages to the courts which the property of an employer furnishes, is it possible to compel him to employ any given number of men on certain prescribed terms. Freedom to accept or reject proffered terms of employment, and freedom to manage one's own business, are essential to sound economic relations in a free community. Experience has proved also that the compulsory feature in the Canadian Act is almost impossible of enforcement where either of the parties considers it advisable to refuse to submit its case to a board. When such refusal has taken place, however, it has usually been on the supposition that the acceptance of the award of the board was essentially compulsory. Thus, it is only the voluntary nature of the ultimate settlement which renders the compulsory submission of a case to a board at all workable." Professor Shortt also makes it clear that the proceedings of a board are as different as possible from those of a court of law. Minor points of difference are disposed of in conference, partial concessions won now from one side, now from the other, until the differences which cannot be reconciled by mutual agreement are reduced to a minimum. At this stage the board generally submits its own proposals for a settlement to the parties. But, should these be rejected, it does not regard its functions as at an end. It proceeds to negotiate—often through the agency of the chairman—with the two parties separately, without bringing them again into conference. "The object of these final negotiations was to find, on either side, the lines of least, and also of most resistance; to overcome prejudice; to plead what seemed to the board or the chairman as the just cause of each side with the other, and gradually to break down or dissolve away the barriers between the parties until so little remained that it was not worth while to risk a great and uncertain struggle for so small an ultimate advantage, even if successful." "It is not so much a question of expounding economic principles as of the diplomatic handling of human personalities, the elimination of misconceptions, the removing at once of sensitive

## The Settlement of Trade Disputes in Canada. 23

suspicion, the memory of old struggles, and the unwillingness to exhibit the apparent weakness of receding from a stand once taken." Professor Shortt favours the exclusion of the press from the proceedings. It is not desirable that the extreme claims of each party "advanced with confidence and backed with vigour," and the inevitable declarations that no reduction of these claims is possible, should be made public and widely advertised, for subsequent concession and withdrawal will be made much more difficult by such publication. The presence of the press also encourages the tendency to "talk to the gallery," while the legitimate interest of the public in a dispute is sufficiently satisfied by the ultimate publication of the board's report. The Canadian system obviously does not lend itself to the establishment of a code or even the creation of a body of "case law" on points of difference likely to recur in industrial disputes. But Professor Shortt mentions certain general principles on which the boards have insisted. Of these the first is the "recognition of unions, in the sense that there shall be no discrimination against their officers or members." The second is "the principle of the open shop," which lays it down that membership of a union shall not be a necessary condition of obtaining employment, and that all agreements made shall be applicable to unionists and non-unionists alike. (It will be remembered that in New Zealand the Court of Arbitration has frequently laid down in its awards that preference shall be given to unionists, subject to certain safeguards and limitations.) Thirdly, undue interference with the liberty of the employer to "manage his own business," in so far as the making of rules and regulations and the promotion of employees is concerned, has been consistently discouraged. Professor Shortt made no extravagant claims for the Lemieux Act. He concluded his address in the following terms:—

"The policy and method of the Canadian Act by no means affords a certain remedy for industrial disputes. No practical man dreams that industrial disputes can be prevented from occurring, because there will always be cases where justice unavoidably pertains to both sides. There are, however, many disputes which are chiefly due to historic prejudice, mutual ignorance and misunderstanding, and it ought to be possible to dispose of most of these, and to effect a working settlement in the case of many of the others. All that one may claim for the essential features of the Canadian Act is that, if tactfully handled, they provide a reasonable method of securing the maximum of concession with the minimum of compulsion."

The example of Canada is in some ways of more practical value to Great Britain than that of Australia or New Zealand. For in

considering legislative possibilities, the general attitude of the people towards governmental intervention must be carefully weighed, and Canada is probably not less but more individualistic in her traditions than Great Britain. The success of the Lemieux Act augurs well for the policy which has been consistently followed by the Board of Trade under Mr. Lloyd-George and Mr. Churchill, which has already been applied to the railways and to the shipbuilding industry, and which, it is to be hoped, is at the present moment in course of application to the cotton trade.

## THE EROSION OF LAND.

A REPORT of the Oceana Company has recorded the fact that the steamers on the Shiré River had been laid up, owing to "the gradual and persistent lowering of the level of Lake Nyassa, and the consequent shallow state of the waters of the Shiré, which is now navigable for a few weeks only in the year, a state of things which could not possibly have been foreseen some years ago." The process which is going on here is unfortunately widespread. The earth is in many places gradually losing its water and soil. The elements of fertility are dispersed in the lakes or the unfruitful and inhuman oceans. In such countries as Palestine, once prosperous and happy, now arid and desert, the process has in no great time completely changed the character of the land. Many parts of Africa, America, and Australia are threatened with the same fate, and no land problem concerns the British Empire more. The wearing away of the carpet of the Veldt in South Africa is perhaps the most serious aspect of the economic trouble in that country. The primitive plain, the recent creation of cosmic forces, is undenuded, but the flow of water over it gradually roughens the surface by cutting out channels, and valleys are formed which have steep sides and narrow bottoms. These ravines in course of time are cut deeper and carried further back until they approach base level, when flats are developed and a state of erosion is reached. Erosion is now, speaking generally, increasing. It means for practical purposes the multiplication of water courses and the increased removal to the sea of fertile soil. The unfortunate fact is that not only natural causes but the progress of civilization tends to this. Man interferes with the provision of nature by felling trees, over-grazing, and other disturbances. In India, hundreds of square miles along the foot-hills of the Himalayas have been in danger of being converted into a desert by being gradually covered with

detritus washed from the denuded hill-sides. This denudation is attributed to over-grazing. But the chief cause is the destruction of forests.

Nature herself is a soil producer, and if left to herself makes the necessary adjustments. She protects the soil by a vegetation which supports and replenishes it, thus increasing the fertility, and which also acts as a store-house for water and a barrier against erosion. But this process of soil formation is slow; it has been calculated roughly at one foot in 10,000 years. It does not require much surface wastage to destroy the constructive work of enormous periods. Water is the great transporting and dissolving force of the world, and if wrongly treated becomes an immense power for mischief.

Trees and other roots bind the soil together and prevent its being wasted. Where all trees have been destroyed, the result is seen in a dry and unfertile plain or slope, intersected by water-courses. A natural forest fire may bring this about as well as the demands of humanity, and probably vast wastes have been caused in this way. Fire also destroys grasses and reeds, which form storage for water. Roads and railways obviously help the running away of water. They are generally laid along low ground and become drainage lines. Large herds of cattle will make deep and dusty paths, which largely contribute to waste of water and soil. They naturally follow the slope in their passage to water, and the track makes an easy water-course.

It is easy to suggest that the cause of the bare plains is the diminution of the rainfall; but any such theory assumes a good deal. The process which has changed a garden into a wilderness must, on this footing, have resulted from a transformation from abundant rain to hardly any rain at all. For such a phenomenon there is no scientific evidence. Allowing that in remote ages the deposit of moisture was greater, there is nothing to show that since the earth settled down more or less comfortably into its present condition the rainfall has decreased. It is asserted frequently in particular localities that it has, but a succession of droughty seasons—a common instance of periodicity—is enough to set up this belief. The probability is that the rainfall, depending as it does on atmospheric causes which remain practically constant, varies little from age to age unless the surface of the land is changed. The South African Inter-Colonial Irrigation Commission remarks that a period of drought distresses men's minds and recalls similar periods to their memory, thus causing an exaggerated judgment. The considerable alterations in the land, which we actually see going on, are at any rate largely due to other causes which can be easily traced.

It is often considered that the dryness of some countries is largely due to the scarcity of vegetation, and that more rain would

fall if there were more trees. No doubt great masses of forests would tend to increase the rainfall, but there is no evidence to show that natural conditions are greatly affected by trees. Rain falls because under certain atmospheric circumstances it must; it is dependent on air currents which are not largely affected by the surface of the land. On the other hand, trees cannot cause a fall of moisture which is not there. Their principal function in the matter is to conserve water when they get it, and with this water the soil. They are one of the means of preventing the rainfall from running rapidly away, and in the course of doing this denuding the soil and silting up the lakes. The forest humus acts as a sponge, letting the rain-water trickle gently and evenly down. Without trees the fertile valley will in some climates become as dry and fruitless as the hill-top land bared by the rains of thousands of years.

Trees in masses may produce rain in two ways: (1) by cooling a warm current of air, so that the vapour in it loses by condensation its gaseous form and turns into minute specks of water; (2) by increasing the amount of vapour in the atmosphere. It is very doubtful how far the first process goes. In some climates, especially in summer, the air in large forests is cooler than that outside, and this air on rising expands and may be cooled below the dew point. Experiments at Nancy have shown that more rain falls in the forest than just outside (100 being taken to represent the fall at the centre, that outside is 76·7). But these experiments, while showing the facts, do not establish the cause; and it seems probable that the cooling effect of forests must be slight. At night trees are generally warmer than the surrounding air, and in the day-time the difference is small, but no doubt enough to cause moisture to be deposited in calm weather. More important is the adiabatic cooling caused by the air rising over mountains. The principal factor in the case is probably the generation of aqueous vapour by the transpiration of plants. "The amount of water-vapour transpired by plants is stated by numerous authors to be enormous. Each tree appears to act as a capillary tube pumping up water from the sub-soil to evaporate it when the work for which it was required is accomplished, through the millions of pores and stomata of its foliage. The surface exposed is very large and the amount of water-vapour given off to the surrounding atmosphere must be considerable. Sachs states\* that 'in the course of a single period of vegetation, the quantity of water which has been withdrawn by evaporation may exceed many times the weight and volume of the plant itself. It is easy to understand that this is possible only when the loss is compensated by the absorption of corresponding quantities of water through the roots, and that the water withdrawn from the leaves is replaced in this way.' The source from which this water is drawn is itself the

\* *Text Book of Botany*, p. 598.

result of forest growth : surface drainage is checked and a large quantity of water is conveyed by percolation to the sub-soil, from whence a part drains off as 'sub-soil drainage' to feed the springs and rivers, and a part is pumped up by the trees as stated above."

—*Mauritian report on déboisement.*

The chief cause of these changes is not temperature but light. It has been found that the amount of water given off is hardly affected by any changes of temperature; but in bright sunshine leaves have been found to give off more than their own weight of water, while in total darkness the output was hardly perceptible. This process under which water is separated from the other constituents of plants is a source of electricity, and to this the afternoon thunderstorm is often attributable.

Thus on the whole there is at least a strong probability that forests increase the fall of rain. But the fall is mostly local, and if this were all it would not have much importance. The essential point is that forests keep much of the moisture. It has been found in experiments made in France and Germany, that evaporation from a forest is only 40 per cent. of what it is in the open. The absorption of the rain in the ground, as contrasted with a surface run-off, is helped by the covering of roots, dead leaves, and loose soil; the mulch of litter keeps the mineral soil below in the best condition for rapid absorption. Of this moisture perhaps half is lost by evaporation and transpiration, but of this some comes back eventually; the other half is discharged gently and steadily into the streams. It is clear that this process of percolation contributes vastly to the permanence and regularity of flow, and that when it is removed desiccation and floods set in with destructive results to the soil.

Thus the most important function of forests in this respect is the prevention of erosion and the modification of surface drainage. It has been found that, when a forest has been destroyed, a heavy rainfall, with nothing to check its course, has drained off in a few hours a watercourse which had been previously fed by subsoil drainage throughout the year and preserved a uniform flow, and in doing so had carried away a large part of a mountain. In France "the usual results have followed the cutting of the forests, in the frequency and destructiveness of floods, which have washed away the soil from the hill sides and valleys of many districts, especially in the South, and the frequent inundations of the last fifty years are no doubt caused by the deforesting of the sources of the Rhone and Saone. Laws were passed in 1860 and 1864 providing for the 'reboisement' of the slopes of mountains, and these laws take effect on private as well as state property. Beneficial results have already ensued. Thousands of acres are annually planted in the departments of Hautes and Basses Alpes; and during the summer of 1875, when much injury was done by floods in the south of France, the

Durance, formerly the most dangerous in this respect of French rivers, gave little cause for anxiety, and it is round the head waters of this river that the chief plantations have been formed.”—*Encyclopædia Britannica*.

In South Africa the process is shown by the following description in the *Cape Agricultural Journal* :—

“The steep mountain slopes of Zwartberg on the North and the Lange Bergen, Outeniquas and Zitzikama Mountains on the South, are drained mainly by a great number of short torrents, the floods of which have increased in violence and capacity as the steep rugged mountains have become deprived of their original dense covering of vegetation. Instead of these streams providing an abundant supply of perennial water which might be utilised for irrigating the rich Karroo alluvium of the main valleys, they now come down in sudden and violent floods which are too strong and of too short duration to be utilised for irrigation excepting to a small degree, most of the flood water flowing away to the sea. The raging volume of water, heavily laden in its upper reaches with coarse and unprofitable sand from the Table Mountain sandstones, on reaching the comparatively level valley deposits its useless burden on the land it inundates, and at the same time tears away vast quantities of the much finer rich alluvium of the Karroo, Uitenhage series, and Bokkeveld, and carries it off to the sea and helps to swell the dimensions of the great Agulhas Bank.

“During the past summer the Oudtshoorn irrigation furrows have been dry, and the Lucerne fields have been parched for want of water, and farmers have been buying mealies with which to feed their ostriches. When rain finally fell in the autumn, and dirty torrents came down from the mountains, none came from the Karroo; one wonders what percentage of the flood was saved from the sea, how much useless silt was deposited on the lands, and how much good alluvium was carried away. Nowadays, whenever really heavy rain falls in the mountain area, we hear of great damage to property, bridges swept away, lands either washed away or great sluits formed through them; or they are rendered useless by being covered with sand and boulders. Let anyone roam about these rich valleys, and he will see everywhere the signs of recent devastation by floods. Big sluits, boulder and sand-strewn flats of once rich arable land, the remains of a great road bridge, &c., and, if he wanders along the banks of the now dry and stony river, he will see its banks everywhere caving in and exposing a great depth of rich alluvial soil. The river is ever increasing in width, and in place of the rich alluvium there is a vast deposit of boulders and sand. As these boulders are deposited further and further down the river, its bed gradually rises, and floods thus

slowly rise above the level of the country, denuding it and opening up fresh channels."

In the same publication Mr. Van Rooy writes as follows:—  
"It is not yet fifty years ago that our fathers left us these regions in a very useful condition, and if we had continued building upon their good work and improved the veld step by step, our farms to-day would certainly be able to carry stock and produce so much more as to carry a more dense population and that no Afrikaner need trek to the Argentine or elsewhere. At present we have to import annually into this large country for its small population millions' worth of provisions. Is that not strong testimony against us? Man certainly has also a responsibility to posterity, and it is nothing less than our sacred duty to see that the ground, as far as it lies in our power, is left to our children in better condition than we received it. Only then there can be progress. And in that respect we stand condemned, for anyone can see that these parts have deteriorated instead of having been improved. Thirty or forty years ago this stook-country was still sound, with magnificent 'vleis' waterpools, and fountains. The veld was closely and densely overgrown with grass and other growth, shrubs, reeds, and 'matjesgoed,' provided with 'blauwbos' and 'taaibos' and an abundance of useful wild tress. We scarcely knew of 'sluits' and noxious weeds, and notwithstanding drought, which at that time occurred also, this was a country of which the majority of years one almost might say: It was as flowing with milk and honey. And what is it now like? Bushes and trees have disappeared almost without leaving a trace, grass and bush largely replaced by noxious weeds and bare, half-dead ground. It is 'sluit' after 'sluit.' The earth is washed to pieces. In one word: It is regrettably deteriorated and lived out, that it is half dead. But I have not yet mentioned the worst, which is the loss, the irreparable loss, of our richest and most fertile soil. The ground, which might be of the most use in maintaining our veld and in storing the indispensable rain and spring-water. Where there used to be the glory of our soil, one now finds sluits of various sizes and bare, hard, dead sub-soil, and where is that treasure? Gone to sea. The cream and fatness of our country is in the sea. And the sea never returns it. Of course, it has taken centuries to form such a deep, fertile top-layer of mould, and how much of it has disappeared for ever during the last 25 years, and how much is still being lost annually while we scarcely take the slightest notice of it? That rapid impoverishment of the choicest of our soils and water is nothing but a national calamity. This gnaws at the root of our individual and national existence. That is the blood and marrow of our country, and if nothing can be done against the fatal

exhaustion of those two indispensable elements of life, then, indeed, one need not be a prophet to see what must be the end of it all."

In cold climates frost acts as a useful conserver of the soil. The agricultural wealth of Canada is in no small measure due to the fact that the valuable nitrates of the earth are held secure by frost, at a time when but for this they would be washed out. But in dry, hot and dusty climates there is no such preservative. Furthermore, the surface soil becomes more loose and friable, and every devastation leaves the ground smoother and more favourable to the easy escape of moisture. Thus when the process of drying up once sets in it is likely to go on at a rapid rate and to end in complete devastation, leaving a land of more or less bare rock and great rivers. This development is going on day by day, and accounts for the increasing wastes which in former days supported flourishing communities. The exhaustion of coal and other mineral resources is a small matter in comparison with the loss of soil. The one is a loss of wealth; the other is extinction.

The most effective method of dealing with the mischief is to reproduce the original conditions by irrigation works. In former times a flood spread in a broad sheet over the land and moved off slowly, depositing soil as it did so. The problem is to do this artificially, but it is no easy matter, as unless great care is taken the diversion of flood water may do more harm than good. Storage reservoirs, or weirs with channels on each side can be used on a flat country. On hilly or undulating ground the most practicable remedy is to obstruct the channels. Stones and bush are useful materials, strengthened, if possible, by wire netting. As soon as sufficient soil has been deposited some suitable shrub should be planted; without this the improvement is not likely to be permanent. Lines of shrubs laid at right angles to the general fall of the land, and so athwart the course of water, check the flow and catch the sediment. *The Cape Agricultural Journal* recommends the American aloe for this purpose. A bank is quickly formed by the silt, and both surface and underground water is held up. The land above is enriched, and the land below is protected. The fleshy leaves of the aloe are said to serve as a palatable food in times of drought.

Roads are often bad offenders, lying as they frequently do, in low places, where they naturally lend themselves to the escape of water. The remedy is to lay them on local ridges, or to raise them slightly above the level of the ground.

Railways should provide as many openings through the line as possible, but the water after passing through a culvert should be distributed in a thin sheet, and not in a stream. In India it is a common practice to dispense with culverts and to form a bank of stones, which are loosely packed, so that the drainage finds its way through without developing anywhere into a stream. This plan is,

of course, only suitable on level ground where the water has no great force.

The heroic remedies must be left to Government action; but in general the mischief is one that can be largely dealt with by individual action. It is not always great measures that are wanted, but careful attention at every point. The remedial measures are simple and cheap, but to use them efficiently the ground must be carefully studied, and the best man for this purpose is the farmer himself. If water is stopped in one district it will try to find another course. The object is to prevent this and establish an even spreading over the land. Every plantation helps this, providing—an essential qualification—that it is laid athwart the course of drainage, and all work of this character contributes to stop the deterioration of the land.

It follows from the above that schemes of re-afforestation should be devoted to the river systems. No harm is done by déboisement on the tops of hills, except around any headwaters of springs and streams: in such places and on the slopes every tree should be retained to prevent flooding and erosion and to retain soil and sub-soil moisture. New trees should be placed in lines at right angles to catch moist winds and induce the precipitation of the moisture.

## THE COLONIAL OFFICE AND THE CROWN COLONIES.

AN interesting paper on British Colonization in the Tropics was read at the School of Commerce at Brussels last February, by Mr. W. L. Grant, Beit Lecturer in Colonial History at Oxford, and has been printed in the March number of the *Revue Economique Internationale*. So much adverse criticism of Belgian colonial methods has proceeded from English sources, that Mr. Grant may have felt his position to be a somewhat delicate one. At any rate, he devoted himself to criticism rather than to laudation of British achievements in this sphere, and we are not sure that the general tendency of his paper is not to give a somewhat unduly pessimistic view of the methods of administration in the Crown Colonies and Protectorates. "Great Britain," he says, "has achieved many triumphs in the domain of colonization, but examination reveals that these triumphs have always been won outside tropical regions." We are not prepared to subscribe to this general statement. It is not easy to deny the title of "triumph," for example, to the results achieved by British rule in the Federated Malay States, and we are disposed to think that the same word might be applied without exaggeration to the work now in progress in Northern Nigeria and the Soudan. When, too, Mr. Grant says that "the West Indies are the Cinderella of our Empire, and I see no fairy godmother on the horizon," he appears to us to go somewhat beyond the truth. To complain of depressed circumstances and of the apathy of the powers that be has long been recognized as the prescriptive right of the West Indian, and it is still conceded to him as readily as it is to the British farmer. But its free and lawful exercise ought not to blind the observer to the existence of a considerable degree of material prosperity in our West Indian Colonies; and we have recently had occasion to point out that there has been a substantial increase in this prosperity of late years. But Mr. Grant's account of

the English Crown Colony system, his explanation of its justification,—the impossibility of placing full powers of government in the hands of a local white minority,—and many of his criticisms of its imperfections, are valuable and instructive, and a foreign audience must have found them of considerable educational value. He compares the methods of selection and training of administrative officers for service in the Colonies unfavourably with the methods applied for the same purpose in the case of India, and in this criticism it is impossible to disagree with him. But it must be remembered that the colonial service has only recently grown to anything like its present dimensions, that lack of funds precludes the immediate adoption of so costly a machinery as that of the Indian Civil Service, and that considerable advances in the direction of more systematic selection and training have quite recently been made. It is fair, too, to point out that there are advantages in maintaining one branch of the public service the conditions of admission to which are sufficiently elastic to admit men of varying experience and training who would scarcely have succeeded in passing through the meshes of a competitive examination. We are not quite sure that we fully understand Mr. Grant's attitude on the subject of the proper relations of administration to commercial interests. He condemns administration by commercial companies as tending to sacrifice sound government to the security of dividends; and he holds that the commercial man requires to be kept under "a strict though enlightened supervision." But he would like to see officials recruited more largely from the commercial classes, commerce more largely represented in the local councils, and "a committee or committees of expert business men, such as are the Associated Chambers of Commerce of the United Kingdom, appointed to take part in the selection of the governor." Upon this subject we find ourselves in disagreement with Mr. Grant. We agree that the promotion of commercial progress is one of the proper functions of government, especially in our Crown Colonies, where "state socialism" in all its branches is already highly developed, and due regard for, and comprehension of commercial interests is certainly essential to the success of administration. But, on the other hand, the interests of the commercial community and those of the native population come not infrequently into conflict, and when this occurs, the government is invested with the duty of arbitration, a duty which it cannot possibly perform impartially and successfully if it is closely associated with, or even dependent for its existence upon, one of the two interests which have come into conflict. The Government of India is not generally charged with a disregard of commercial interests. Yet no government has a *personnel* so wholly aloof from commercial connections. The ideal system would seem in fact to be that the

administration should be accessible to all interests but identified with none.

There is one other point on which we feel disposed to quarrel with Mr. Grant, and that is his description of the staff of the Colonial Office. We quote, but forbear to translate.

“J’y connais des hommes de grande valeur qui connaissent à fond la littérature grecque et latine; qui n’ont jamais mis les pieds hors de l’Angleterre, si ce n’est pour aller prendre les bains de mer ou les eaux en France; qui voient dans toutes les colonies actuelles une source d’ennuis, parce qu’elles leur prennent un temps précieux qu’ils aimeraient consacrer à étudier leur histoire aux XVII<sup>e</sup> et XVIII<sup>e</sup> siècles; est-il donc extraordinaire que ce ministère ne satisfasse pas les colonies? De fait, au temps passé on encourageait les employés à ne rien savoir sur les colonies: leurs jugements auraient pu être prévenus; bien qu’une telle disposition d’esprit n’existe plus, ils sont encore trop peu nombreux les employés des ministères des colonies, qui ont des renseignements de première main sur les colonies.”

Mr. Grant, we think, underestimates the amount of first-hand knowledge of the Colonies possessed by members of the Colonial Office, but apart from that point we suspect that his criticism is based to some extent on a failure to appreciate the exact functions of the office in its relations with tropical dependencies. The criticism which we have quoted largely ignores the administrative staffs in the Colonies. The Colonial Office criticises, controls, and assists administration, but it is not its function to administer. For these purposes it must be closely in touch with colonial officials, and this it certainly is, but it is not an absolute necessity that its members should have a local knowledge of the Colonies. The visits which they are occasionally able to make to the Colonies are valuable mostly as encouraging sympathetic appreciation of the work done and to be done, and supplying a skeleton of concrete experience upon which “paper knowledge” can crystallize more easily, but the knowledge acquired soon gets out of date, and it would obviously be unsafe to rely much on it. Nor is there any occasion to do so, for not only is the stream of information supplied by mail on the whole extremely full, but a great number of officers, averaging about 600, are at home on leave, and most of them are frequently in communication with the office. Any attempt by the civil servants at home to judge colonial questions upon facts which they have themselves collected is sure to be dangerous, and the suggestion that it should be done shows a confusion of two totally distinct provinces of work. The essential question is not how much the handful of men in the Colonial Office have seen of the Colonies, but how the local work is done by the men who are sent out to do it. We shall hardly be suspected of underrating the importance of

the examination and control kept up by the Colonial Office, but the occupation is entirely different, and with it the qualifications. In any case we are sure that Mr. Grant is entirely wrong in suggesting that the staff is distracted from its current work by either its reminiscences of Greek and Latin literature or researches into the history of the XVIIth and XVIIIth century. We suspect that Mr. Grant himself would plead guilty to some proclivities of this kind, without admitting that they necessarily impair his efficiency for practical work. In the Colonial Office it is very certain, whether fortunately or unfortunately, that they are not general.

## ANURADHAPURA.

[This buried city of Ceylon—the Anuro-Grammum of Ptolemy—was founded about 500 B.C. and became the capital soon after. Its importance increased when Ceylon embraced Buddhism about 300 B.C. A branch of the sacred Bo-tree, under which Buddha attained wisdom, was brought here from India; it is now the oldest historical tree in the world, and attracts great crowds of pilgrims—20,000 or 30,000—on the full moons of May, June and July. The ruins of the city were neglected for many centuries, but some thirty years ago the government began a work of restoration. The following has been written by one of the engineers who were engaged on it. The clearing is still going on; during 1904 and 1905 the monastery was excavated.]

WHAT memories are called up by this ancient jungle-covered city, preserved from the weather for more than a thousand years! A few years ago the word “Anarajahpoora,” as we called it, meant the most unhealthy district of Ceylon, and now we hear of it as a show place, and as healthy as any part of the island. A few years ago only we were making roads there, and clearing the jungle away from the ancient ruins. And yet how perfect was much that we found! The moonstones, as we called them, at the bottom of the flights of steps into the houses, were half circular in form, and often beautifully carved in high relief. The handrails were as perfectly wrought as if they had just left the mason’s hand. There must have been wonderful woodworkers in Anuradhapura, at least, if we may judge from the stonework left, for evidently the stonework was an imitation of the woodwork, which no doubt was chiefly used for the upper part of the buildings. Perhaps there is no finer stonework in the world than here, but the stone is wrought as if it were wood.

Stone is used everywhere as a veneer to brickwork, and the high state of finish to which it was brought can only be compared with woodwork of the highest excellence. We may take it for granted then that the woodwork of the place must have been magnificent, for surely, if stonework has been wrought so perfectly in imitation of woodwork, it is only fair to imagine the woodwork at least as perfect.

The temple of the thousand pillars seems most likely to have been a wooden structure on a stone foundation. Now this stone foundation is merely rows of squared stone logs, as it were, set up on end, and used as we would use wooden uprights for a foundation now. This must have been a vast building, but there is no trace whatever of its superstructure, or of its architectural form. The private dwelling houses in some places were set at more or less equal distances apart on each side of a great thoroughfare, and as the stonework alone is left we have to conjecture what their appearance must have been. The stonework, as we have said before, is only an imitation of woodwork, so we find the uprights with tenons to fit into the horizontal stones which lay across them, to support, no doubt, the wooden superstructure. This woodworking style is carried out in the capitals of columns, for they have a mortice cut in them, and on the column will be found the square tenon which fits the mortice. When we come to the examination of the Tuparama Dagoba we find the woodwork style still adopted in the columns which are, as a rule, squared logs of stone set on end. In this ruin some of the columns are many sided, but though the general plan of the place is round, the columns have in no case been set radially from the centre. This is a most curious fact, and in making plans of these Dagobas, symmetry, as we understand the word, is not to be expected. This Dagoba, and Ruanwelle, perhaps the largest building of the kind in the world, would require many pages to explain how they were built and for what purpose, but they stand before us as monuments of a great religion to this day, and at certain seasons the Ruanwelle Dagoba is visited by hundreds of men, women, and children, who camp round it and seem to have a picnic, which is brought to a close by the great concourse mounting the platforms which surround its base, and swathing the walls of these platforms with cloths and fabrics tied together. The continuous shouts of "Sadu" have an impressive effect when heard from a distance. Evidently these celebrations come down from great antiquity, and though the Buddhist priest here reads his "Novum Testamentum," and highly approves of its teaching, he has before him a religious system which to him is satisfactory and absolutely free from strife. The Buddhist is an amazing instance of hereditary religious thought, and in Anuradhapura his gentle listlessness seemed worse than useless as a force in the world. It is here that the sacred "Bo-tree" with its masonry protection can be seen, but it does not, apparently, attract either the priests or the people, so the wild monkeys can enjoy it by themselves. Our jungle clearings before the present finishing touches of civilisation had reached this part gave the appearance of an English park to the place, and though tropical creatures of all kinds were met with, the sparrow was there and the swallow, to make the Englishman feel at home.

There were two immense public baths, as we thought them then, in a remote part of the jungle, with stately stone staircases, with finely wrought handrails ending on the landings in artistic curves. These ruins were in such good repair that it was hard to believe that they were built more than a thousand years ago. There was one curious circular well near the Dagobas with accurately sloped sides. This well was built of brick and lined with wrought stone covering, set in steps from the top to the bottom. Ten feet across at the top and about two at the bottom, the depth about twenty feet. But what was it for? In Anuradhapura the question "What was it for?" constantly presented itself without getting a satisfactory answer from oneself or anyone else. But one of the greatest puzzles of all was a large flat stone with a slot cut in it: this stone used to be under water at a depth of say thirty feet when the great tank or lake was full of water. It was at the end of the culvert through which the water was carried under the great embankment for irrigation, and lay flat. Possibly it was the valve through which the water was admitted by the removal of some sort of plug or door. In the middle of the great embankment was a brickwork shaft at the bottom of which the opening into the culvert could be seen. The culvert, in fact, was divided at this point, so the water must have risen in the shaft and thereby insured a continuous and regular flow to the irrigation channels outside the bank or embankment. We had not tried this system of delivery when I examined this interesting piece of ancient water engineering, but were cutting the embankments across, and making use of wing walls and an iron service pipe for delivery. These wing walls were a cause of anxiety because in the dry weather the bank receded slightly from them, and when the rains came water trickled through and weakened the bank where it abutted on the wing walls.

Much can still be learnt from the study of these ancient water works, but it is very difficult to find out when examining Eastern work whether a comprehensive scheme had been carried out, or whether tanks were built wherever a community chose, without reference to other communities which might be affected injuriously by the work.

Anuradhapura, the city of the thousand kings, has secrets which will take years and years to find out, and a visit to it will certainly repay the visitor in letting him see actually how work was done in those remote times, and how patience helped those old stoneworkers in the difficult task of cutting out a great drinking trough for elephants from a solid rock, of which, most fortunately, one specimen was to be seen. As to how the stone beams were quarried square out of the living rock—as we could see they were, for specimens unused were lying in the quarry—who shall say?

## REVIEWS AND NOTICES.

**A History of Canada, 1763-1812.** (By SIR C. P. LUCAS, K.C.M.G.,  
C.B. *Clarendon Press, Oxford.*)

THIS clear and readable history is distinguished from the ordinary style of narrative by the numerous comments suggested, not only by the facts related, but also by the writer's practical experience of recent developments. The method leads to general observations applying both to old and to new situations. Thus, in commenting on the American revolution, Sir Charles Lucas sketches the differences which at any point of time tend to arise between a Mother-country and its Colonies. "A Colonial Empire consists of an old community linked to young ones. The conditions, the standards, the points of view, in politics, in morals, in social and industrial matters, are not identical in old and young constitutions. Young people, like young men, do not count the cost, and do not feel responsibility to the same extent as their elders. They are more restive, more ready to move forward, more prompt in action. Their horizon is limited, and therefore they see immediate objects clearly, and they do not appreciate compromise. The problems which face them are simple, as compared with the complicated questions which face older communities, and they are impatient of the caution and hesitation which comes with inherited experience in a world-wide field of action. The future is theirs rather than the past; they have not yet accumulated much capital and draw little on the coming time. Most of all, being on promotion, they are sensitive as to their standing, keenly alive to their interests, and resent any semblance of being slighted." It may be doubted whether the distinction is not less a question of age and youth, than one of restricted and abundant opportunities. The individual Englishman is probably as open to new ideas as the individual colonist, but in practical life he has less room for them, and is accustomed from childhood to comparatively fixed conditions.

But however the cause may be expressed, there can be no doubt that politically young communities are more plastic than the old, and, to repeat Sir Charles Lucas's words, "more ready to move forward, more prompt in action." The frequent anticipation in Australia of administrative improvements in this country, and the swift decisions come to on occasions appealing to the national spirit, illustrate this rapidity of movement. From the point of view of the administrator, the habit has occasional disadvantages, but it is well to have both qualities, enterprise on the one hand and caution on the other, represented in the working of the Empire.

The book is largely concerned with the American war, the results of which are viewed in the light of present circumstances. The victory of the States seemed at the time to be disastrous to British colonisation. Franklin offered to furnish Gibbon with "materials for writing the history of the Decline of the British Empire." As it turned out, the wide and stable expansion of the Empire was the direct outcome of the loss of the American States. Within four years after the treaty the occupation of Australia began, and the building up of Empire went on apace. The separation of the States, inevitable in the long run, came early enough not to interfere with this movement; had it come later the States would have absorbed much of the strength which went to the making of it. Moreover, in the new creation the moral lesson was of enormous value. As regards Canada the consequences are vigorously summed up: "The result of the war was to give prominence and individuality to Canada as a component part of the British Empire; to bring in a strong body of British colonists not strengthening but supplementing the French Canadians and antagonistic to the United States from which they were refugees; to revive the instinct of self-preservation which in old days had kept Canada alive, by again confronting her with a foreign Power, and at the same time to give her the advantage of protection by and political connection with what was still to be the greatest sea-going and colonizing nation of the world. The result of the War of American Independence was to make the United States a great nation; but it was a result which, whether with England or without, they must in any case have achieved. The war had also the effect, and no other cause could have had a like effect, of making possible a national existence for Canada, which possibility was to be converted into a living and a patent fact by the second American war, the war of 1812."

Whatever may be said on the merits of the case of independence, it is clear that no similar situation will ever arise again. The early English colonists went out to America largely in the spirit of protest against the conditions at home: they were more or less ripe for revolution and separation on an opportunity, and the opportunity soon occurred. The whole spirit is different now;

there is neither resentment on the one side, nor arrogance on the other. The only trial which would put the connection of Canada with the Empire to serious test would be a great war, and it is easy to appreciate the feeling which has been expressed by Mr. Bourassa that many Canadians, the French element in particular, have some dread of being involved in a struggle over some question in which they are little concerned. If such an unfortunate occasion ever arises, the sympathy and support of Canada would no doubt largely depend on the view taken in the Dominion of the merits of the case; if that view were clearly on England's side, there can be no moral doubt that Canada would stand by the Colony.

We cordially commend Sir Charles Lucas's book to all readers who wish for a straightforward history of the period, not overloaded with detail, but full of suggestive criticism.

---

### The British Empire: its Past, its Present, and its Future.

(By A. F. POLLARD. *League of the Empire, Carlton Hall, Westminster.*)

It is stated in the preface that the object of this volume and its successors is, like those of the League of the Empire itself, primarily educational, and that the expenses of the series having been already provided for, all the proceeds will be devoted to the furtherance of education. It is very satisfactory to find that a work written with these objects is eminently readable. It brings into prominence the material fact and abounds in interesting comment. The concluding chapter will be the most attractive to the general reader. It deals with the question of the future organisation of the Empire, and puts strongly the case for administrative combination between the Mother-country and the Colonies. A machinery has been provided in the Imperial Conference, and we agree with the author that it will be whatever the Dominions determine to make it. If their Governments insist on finding business for it (and of appropriate business there is no lack), the business will have to be done, and in proportion to the work the needful instruments must be developed. A list is given of the topics of general importance which have been marked for consideration—uniformity of naturalization laws, revision of commercial treaties, uniformity as to trade marks, patents, trade statistics and company law, and the "all red" route to Australia. It can hardly be claimed, however, that the list is an inspiring one. With the exception of the last subject, it is limited to technical matters, and experience has shown that these must be in effect settled by experts, and that political leaders have little time or desire to meddle with them. The most important of

such questions—uniformity of shipping law—is not included, and the correspondence which has taken place on this subject shows the difficulty of establishing uniform rules. Uniformity, in fact, in such matters is more than can be expected: the aims and policy are different in different places and dictate varying requirements. The ordinary machinery is sufficient to carry on the discussion of such subjects, and a vast amount of work is continually being carried on in this way, but without coming prominently before the public. The value of the Imperial Conference, however, is not to be measured by actual results in these, or indeed, any other matters. The fact of the periodical meeting of the political chiefs of the Empire is by itself of enormous importance in consolidating the connection, the strength of which lies in the hearts of the men who influence thought and action. There will always be opportunity and occasion at these meetings for the expression of friendly feeling and harmonious desire, and an impulse will be given to the forces which make for combination and mutual support.

---

**The Commonwealth of Australia.** (By B. R. WISE. *Sir Isaac Pitman & Sons.* 7s. 6d. nett.)

This volume, the first of an "All Red Series," is quite distressingly "all red" in external appearance. The redness of the edges vies with that of the cover, and the redness of the cover easily communicates itself to the hands of the reader. But the inside is much better than the outside. Mr. Bernhard Wise has an intimate knowledge of Australian affairs, and a not less intimate knowledge of the ordinary attitude towards them of the British public. He therefore knows what misconceptions have arisen or are likely to arise, and he is well qualified to remove them. But he admits,—and in justice to English critics of Australia the point deserves emphasis—that most of the stories circulated to discredit Australia "originated in some Australian newspaper or some speech by an Australian politician." "In Australia, Parliament and the Press cry every error of Australians through a megaphone." One reflects that it is not for nothing that Australia possesses a population of almost purely British origin. Mr. Wise understands that in Canada you can be fined for publishing a libel on Canada. "Such a law," he reflects "would have augmented the Australian revenue." The Englishman who reads Mr. Wise's book carefully will have no further excuse for misunderstanding. He will find the charge of general political corruption most energetically repudiated. He will find the picturesque legend of the six hatters traced to its origin and reduced to its true dimensions. If they had happened to pursue some other calling it is not likely that their fame would have encircled the globe. But there is something about a hatter which

arrests the imagination ; and during the happy days of leisure when they paced the streets of Sydney and returned each evening to their ship, their employer enjoyed a splendid gratuitous advertisement. We do not wish it to be understood that Mr. Wise invariably identifies himself with the Australian point of view. He is not less severe than other writers have been in his strictures on the national devotion to betting, and he can find little to say in justification of Australian cookery. He is ready too to admit the defects of Australian Parliaments—the extreme prolixity of debates, the time wasted on aimless motions, the irresponsibility of the private member masquerading as freedom from party ties, and in the case of one State, the unrestrained license of language. But he leaves one with the impression that he regards himself as primarily a citizen of Australia, and that he is proud to be able to claim the title. The most valuable section of the book is Part II., which describes how the machinery of Government actually works. He tells the history of the establishment of the Commonwealth, in which he was himself an actor, and explains the peculiarities of its constitution by reference to their origin. In speaking of the old Federal Council, he quotes the following criticism written by himself in 1885. “It originated in no Colonial Parliament and was suggested by no popular movement. It is inferior in all the attributes of a governing body. It makes no provision for an executive ; it has no power of taxation ; it cannot appropriate a penny of the Federal revenue ; it contains no provision for an appellate judiciary to decide conflicts between federal and local authority. It is thus a Cabinet without responsibility ; a Government without authority ; an Executive without a revenue . . . It must give rise to numberless occasions for dispute.” We reproduce this passage because its significance is not confined to Australia. It enumerates, tersely and cogently, the difficulties which still stand in the way of any scheme for the establishment of an Imperial Council. Mr. Wise is a convinced Federalist, and he holds that when the growing sense of Nationality in Australia demands fuller expression, the constitution will have to be remodelled on Canadian lines. He points to the decision of the High Court in the famous “Harvester” case, which proved a fatal obstacle to Mr. Deakin’s scheme which goes by the name of the “New Protection,” as a typical example of the way in which the framing of a National policy is frustrated by the existing limitations on the powers of the Commonwealth. In this connection, it is interesting to notice that the safeguard conceded to the State by the grant of equal representation in the Senate, a device copied from the American constitution, and recently reproduced, in a modified form, in the draft South African constitution, has, in Mr. Wise’s opinion, proved to be unnecessary. “It is evident now,” he writes, “after eight years trial of Union, that these demands

undervalued the National sentiment and were based on the delusion that parties would divide upon the issue of Commonwealth *versus* States. In fact, party divisions have never been upon State lines, and are not likely to become so, while nothing indicates that the States will ever group themselves, as a body, in opposition to the Commonwealth." The truth appears to be that, while the battle between the Commonwealth and the States continues, the battleground is not the Commonwealth Parliament. Party divisions in the Assembly and the Senate run upon similar lines, and Sir Richard Baker's dilemma, "There cannot be a responsible Government which is responsible to two Houses," has proved to be an unreal one.

The third section of Mr. Wise's book deals with various legislative measures of the Commonwealth and States. There is a useful account of the Wages Board system in Victoria and of the Industrial Arbitration Law of New South Wales. Mr. Wise was himself responsible for the introduction of the latter, and he naturally regards it as preferable to the Victorian system. The recent attempt to combine the two systems in New South Wales he views with distrust, and considers that it has already broken down. An interesting point which Mr. Wise makes is that whereas the policy of Industrial Arbitration promotes the development of trade unionism, the Wages Board system has an opposite result. This certainly appears to be borne out by the statistics which he quotes as to the membership of trades unions in Victoria, as compared with New South Wales and Western Australia. Mr. Ramsay MacDonald has frequently argued that both systems are only possible as part of a policy of high protection, and are therefore inapplicable to present conditions in England. The question is of peculiar interest in view of the recent introduction of the Trade Boards Bill by Mr. Churchill; but Mr. Wise, as a protectionist describing a protectionist community, can hardly be expected to deal with this particular argument. We note that he is not in favour of the ultra-democratic proposals which have found some support in Australia—in particular the general use of the referendum, and the direct election of ministers by Parliament. Mr. Wise is an enthusiastic supporter of the policy of Imperial preference, and of Mr. Deakin's plan for universal military service. We commend his volume to English readers who wish to obtain a more intimate understanding of Australian politics. In the next volume of the series Sir Arthur Douglas is to describe the Dominion of New Zealand. A little more care might be taken with the printing, typographical errors being somewhat frequent in the volume which we have noticed.

**The Colonies and Imperial Defence.** (By P. A. SILBURN, D.S.O., M.L.A., late Major, Natal Permanent Forces. *Longmans, Green and Co., 6s.*)

This book makes its appearance at a time when the question of Imperial Defence is very much to the fore, and the writer, a Colonial who has served in the field with Colonials, brings to his task a considerable knowledge of the data of the subject, and of the feelings with which it is regarded in the Colonies. The dominion of the seas, which every one agrees would in the event of a great war be essential to the maintenance of the Empire, is viewed in the Colonies and in the Mother-country from different standpoints. "The theory held by the Admiralty authorities, 'that the safety of Colonial ports can be best secured by the operations of a fleet somewhere away out on the high seas,' has yet to be confirmed in actual war; the past is full of historical examples, but the matter-of-fact Colonial mind looks for something fresher than the musty pages of history. To him it appears a matter of rash speculation to risk the safety of Australia in the hands of the Admiralty alone. The Colonial sees many elements of danger in placing his whole trust for personal safety in the hands of a defence force provided by the inhabitants of the United Kingdom; to them the loss of a Colonial possession would but mean the loss of a prestige, or at the worst the partial and perhaps temporary disruption of the Empire." Whatever may be said of the principle of strategic control and concentration, this feeling exists and has to be reckoned with. Mr. Silburn recognizes and strongly deprecates the futility of a policy which, if generally followed, would fritter away the resources of the Empire instead of securing a strong homogeneous Navy, but he also recognises that, on the whole, defence is a question of minor importance in the Parliaments of the younger self-governing Colonies. "In those Legislatures it only receives attention when the Budget is well on the credit side, and when other subjects considered locally of burning import are quiescent. It is first shelved when the Budget is on the wrong side, or a branch railway, redistribution or immigration restriction Bill is brought forward. The heat and turmoil of debate, discipline of party, and the importunities of Colonial constituents preclude most Colonial politicians from examining closely any questions from a point of view other than that of expediency." The attempt to settle the matter by the system of monetary contributions by the self-governing Colonies to the Navy, which results in a bare £400,000, or about 1 per cent. of the naval vote, is unsatisfactory to both sides. At home we find that we pay 16s. per head for naval defence, while the Colonist pays 4d. On the other hand: "The

grievances that most Colonies have against the direct contribution are :—

1st. That when asked for, no proper basis for 'contribution was suggested ; it was left for the Colonies to grant what they thought fit, thus placing them in a very ambiguous position with regard to the Mother-country, the other self-governing Colonies, and the Empire generally.

2nd. That when granted, there is no control by the Colonies on the expenditure.

3rd. That it gives in return no guarantee of naval protection.

4th. It is felt in some Colonial quarters that these naval grants would be more effectually used in the interests of Imperial defence by being expended on local defences."

Mr. Silburn's solution is that Great Britain should provide the Navy and the Colonies assist in the Army. He contends that the population of the great colonies are essentially inland people, little interested in or fit for sea work. On the other hand, they are eminently fit for army work. "Canada, Australia, South Africa and New Zealand are in a position to relieve the Mother-country of a great deal of her military burden. A very large proportion of the Imperial Army should be supplied by these large pastoral Colonies. Then, again, each of these Colonies should be responsible for the adequate land defences of their coasts, the absolute security of the coaling ports and harbours of refuge. In undertaking this at their own expense, and with their own Colonial manhood, they are giving a far more practical contribution to the Navy than can be represented in cash, and more effective defence to themselves and the Empire, than by the selfish and ineffective policy of local and independent Navies."

The merits of the idea are a matter for experts, but, at any rate, it is based on an attempt to follow natural lines. The present defensive resources of every Colony are summed up in a convenient form.

---

"Pioneering." (By F. SHELFORD, M.I.C.E. *E. and F. N. Spon*, 3s. net.)

Sir George Goldie observes in a preface to this book that the traveller has "in this small volume a very complete compendium, which will spare him diffuse and wearisome enquiries at a time when he probably needs to concentrate his attention on what he is leaving behind him at home, or on the work which is taking him abroad. What experienced explorer, if he could be brought to free confession, would not admit his early tortures of indecision as to what he should select and what he should reject in his equipment,

and his subsequent self-reproaches for his sins of commission and omission in this respect?"

Mr. Shelford's personal experiences and his official acquaintance with camp requirements enable him to set out fully and clearly the best provision for a tour or expedition in tropical countries. Every necessary article is discussed, and in particular mention may be made here of the canteen devised by Sir Walter Egerton, said to be probably the most excellent in existence, and sold at the Army and Navy Co-operative Stores, and of the Doulton pump filters (price about 36s.), described as the most carefully thought-out filter at present offered to travellers. It is well to have in mind that all luggage and cases should be of tin, if possible. Mosquito boots, which are necessary to check the insect's special partiality for biting one's ankles during dinner, are now procurable at the Army and Navy Stores. Handy notes are given on mapping and surveying. The "tenderfoot" is warned to be considerate to his carriers, and told that a smile of encouragement or a well-timed joke will put the whole party into good humour and add half-a-dozen miles to a day's march. Unfortunately, no illustrations of this form of procedure are given, but probably most officials have picked up a few examples at the Sports Club or other favourite resorts. We cordially recommend the little volume to all who have occasion to travel in the tropics.

---

**The Frontiers of Beluchistan.** (By G. P. TATE. *Messrs. Witherby.* 12s. 6d. net.)

Those who are interested in the difficulties of survey work will find an example in this book. In two and a-half years the Seistan Arbitration Mission lost 4,900 camels and horses, and endured the horrors of thirst, the visits of road wolves and jackals, and a dry wind of peculiar penetrating power which blows in these favoured regions for 120 days in the year. To preserve them from the sting of the Seistan fly the horses are clad in pyjamas as well as coats. The country seems remarkable chiefly for ruined towns and mouldering monuments. Altogether the colonial surveys with which we are acquainted, though in some cases attended with enough hardship to satisfy anyone, cannot compete with this. The narrative may therefore be read with enjoyment, as showing that things are worse somewhere else. There has been some disappointment among reviewers of this work on the ground that it does not bring out the romance of the country. Possibly this criticism is largely due to the fact that Mr. Tate has lived there and the reviewers have not.

---

**Wellcome Research Laboratories.**—GORDON MEMORIAL COLLEGE, KHARTOUM: Third Report and Supplement (*Baillière, Tindall and Cox*, £1 1s. and 10s. 6d.)

These reports are full of valuable matter of interest to all tropical countries, though why technical works of this description should be got up in a sumptuous and expensive manner is a mystery. Similar productions abroad are issued with cheap paper and binding, and are therefore procurable by the ordinary student.

Medical, bacteriological and chemical observations are set out with fullness and abundant illustrations. Forty-eight coloured plates show the forms of the germs which infest the blood in tropical diseases and the insects which carry them about: the mosquito, the chigger, tsetse and tumbu flies, locusts, buttis, ticks, fleas, and others *ejusdem generis* are depicted with a fullness which shows the wonderful advance of medical enquiry into these mysterious disorders. In the old days Khartoum was a perfect hot-bed of mosquito life, but the plague has been so vigorously attacked that the insect is now distinctly rare there. Rules are given for the construction of irrigation channels in such a way as to prevent malaria: the important point is that they should be on a higher level than the surrounding land, so that when the flow of water in them ceases they may drain dry. Some notes are given on tropical houses, one point of which is that they should be as well darkened as is convenient. The black man is sufficiently protected from the injurious light rays by the pigmentation of his skin, and has therefore only to shield himself from the heat rays; the white man has to shield himself from both, but generally his houses are not so much darkened and therefore not so healthy as the native huts. An account is given of the medical practice and superstition of the natives. Magical beliefs of course play an important part in their sphere, and a scientific examination of the drugs used shows an astonishing absence of any empirical knowledge. In one case the doctor allowed a Hakim to cure a patient suffering from advanced syphilis by a medicine consisting chiefly of iron smelter's refuse, but the patient collapsed (the transaction however interesting scientifically, was perhaps open to some academical objection from this point of view) and the Hakim fled in a fright and was not seen again. The most curious feature of this subject is that "wonderful cures are of course reported on all sides, and the non-professional English official is quite convinced in many cases that the native Hakim possesses mysterious knowledge and drugs far superior to the mercury and iodide of the English Physician." A tribute however is paid to native massage, a universal custom among the Arabs in health and disease. A strongly scented paste is made from ground dura, fat, oil, &c., rubbed over the entire body, and gradually worked off with

a strong kneading action: with this all dead epithelium is removed, and a refreshing tone given to the skin and muscles. In wasting diseases, fever, rheumatism, strains and sprains, no better treatment, it is observed, could be employed. The Arab is careful of his head, and it is pointed out that the thick paste of flour and oil, which is rubbed into the hair and allowed to dry into a perfect plaster cast about an inch thick, is an excellent safeguard against the sun; but the writer is content with the suggestion and does not go the length of recommending the practice as a substitute for straw hats.

The supplement contains a review of some of the more recent advances in tropical medicine. Under the head of "Water" there is a useful account of methods by which water may be purified for domestic purposes. Several machines are on the market for boiling water in such a way as to retain the air in solution, for if this is not done the boiled water has an insipid taste. It should be remembered that the water used for washing up plates, and knives and forks, may, if not purified, infect these articles. The new army cart is fitted with sponges to stop sediment, and with candles to stop microbes. When the soldier is some distance from transport, Vaillard's tablets are recommended; these contain an iodide which kills certain organisms with certainty. Storage by itself is a method of purifying water, one theory being that the micro-organisms of water-borne diseases gradually die in the struggle for existence against ordinary water bacteria. If water is stored for a long time, it becomes incapable of giving rise to epidemic disease, and it is a good thing therefore to have reservoirs of water. Lake water is well known to be at least comparatively pure. Probably storage for four weeks is sufficient, and even a few days have a good effect. In a recent Cyprus report the question is discussed whether reservoirs are dangerous as breeding grounds of mosquitoes, and the conclusion arrived at is that they may be, but that a distance of one mile gives protection from infection.

---

### **A Nyasaland Handbook.**

We have received a copy of the first issue of "The Handbook of Nyasaland," which is published by the Government Printer at Zomba, and may also be obtained (price 3s. 6d. nett) from Messrs. Wyman & Sons, of Fetter Lane. In addition to full lists of the establishments of Government Departments, statistics of revenue and expenditure, information as to postal regulations, lists of court fees, &c., &c, the volume contains an excellent descriptive section, and much information as to the history, population, fauna and flora of the Protectorate. A valuable section is devoted to agriculture, and there are some useful and practical medical notes.

Altogether, the intending settler or visitor will find in this book just what he requires in the way both of fact and of advice, and we offer our congratulations to all who have been concerned in its production. There are some excellent illustrations.

We have received a copy of the Handbook of the Cayman Islands for 1909 (price 1s. 6d.) which is now in its second year of issue. It contains much interesting information about this remote and little-known Dependency.

---

**West Indian Bulletin.**

No. 4, vol. ix., contains articles on the timber of Jamaica and Dominica, the Aleyrodidæ of Bardados, fungous diseases of Cocoa-nuts, and millions and mosquitoes

## BUSINESS NOTES.

### Lighting of Coaches.

The following memorandum has been received dealing with this question. The three methods of lighting carriages, are :—

- (a) By means of oil lamps.
- (b) Compressed Gas.
- (c) Electric Lighting.

(a) This system involves little capital outlay beyond the acquisition of the lamps and globes, but has been considered for many years quite unsatisfactory from a railway standpoint. The light given by the lamps is indifferent ; oil and water find their way into the globes which in turn become more or less opaque ; the leakage of oil, wicks burning irregularly causing smoky chimneys, and the general results from oil lighting have proved very unsatisfactory. In America, especially in the Pullman Cars, light is provided by clusters of oil lamps burning paraffin. These in charge of a careful conductor seem to give very satisfactory results, but the disadvantages are not entirely abolished even under such conditions. In the same way, of recent years, oil lamps in which the flame under pressure and mixed with air impinges on a mantle, thus giving an incandescent light, have been introduced, but broken mantles and other defects have resulted in failure of lights and continual trouble.

Acetylene has also been used but it is not viewed favourably in the Railway world, and is not considered satisfactory.

(b) Lighting by gas has proved much more satisfactory and is in common use in England, America, and on the Continent. It consists of a gas which is manufactured from either crude petroleum or shale oil, the oil being run into a red hot iron retort where the oil is vapourised, and finally converted into gas. After washing and cleaning from tarry deposits the gas is passed into a holder from which it is in turn compressed by a suitable engine into a series of large storage tanks capable of easily withstanding the pressure to

which the gas is compressed (ten atmospheres). From these reservoirs high pressure pipes are laid to the neighbourhood where the coaches are cleaned, stored and sorted, and the gas is led from these mains to small storage cylinders under the coaches by means of flexible hose pipes. Each coach is fitted with a contrivance for reducing the pressure from the cylinders to a constant pressure at the burners, and the result is that a very rich gas is provided in the lamp, the consumption of which is comparatively small. The lighting from this system is good and clean, but it has the disadvantage of requiring a special and somewhat expensive plant to be installed at some point or points on the railway. If the demand for gas is not sufficient to justify a gas plant at each station where the charging of the coach cylinders is necessary, arrangements are made to use a certain number of travelling high-pressure reservoirs, which are charged from the original station and sent to the substations, where small gas mains are again laid to enable the coaches to be properly charged. This system has the advantage of being self-contained in the sense of the word that every coach is entirely equipped and is absolutely independent of the movement of any other coach, so that shunting operations, or transferring the carriage from the main line to a branch, has no effect upon the lighting of the vehicles. A system of lighting by coal gas was in vogue on the North London Railway some years ago whereby ordinary coal gas was stored in large india-rubber bags at one end of the guard's brake-van, led by pipes and rubber connections through the whole of the train; but this somewhat obsolete and unsatisfactory method has been done away with for some years.

(c) Electric lighting has been tried in several forms, principally one or other or a combination of the systems of—

- (i.) Generating electricity on the train and conveying it to the compartments.
- (ii.) Storage battery.
- (iii.) Combination of (i.) and (ii.).

The most successful system, and that generally adopted now, is by "Stone's Patent Electric Lighting." In this system a small dynamo is connected with the axle of the coach and each vehicle thus generates its own supply of electricity. The mechanism is so arranged that a constant supply of current to the lamps is maintained if required when running at anything beyond the minimum speed. When the lamps are not in use, or should the speed be greater than that necessary to supply the power to the lamp, the electricity so generated passes into a small storage battery or set of accumulators, and is there in readiness for future consumption when the train is at a standstill, or proceeding at such a low speed as not to generate sufficient electricity to light the lamps.

To lay down a plant for compressed oil gas suitable for the requirements of a railway might necessitate an expenditure of roughly from £4,500 to £5,000, exclusive of buildings. In England, with oil costing about 3½d. per gallon, the gas works out at about 10s. 9d. per thousand cubic feet. The consumption of oil gas is about three-fourths of a cubic foot per burner per hour, and to thoroughly light a coach duplex burners in each lamp are recommended. In the case of electricity there is no continual recurrent charge for material for the manufacture of electricity, but only the first cost, which is heavy, of equipping the coaches with dynamos, &c. One of the serious disadvantages of either oil or gas consists in the danger of fire in the case of a collision or serious disaster on the railway. Several of the recent accidents to passenger trains on railways in other countries have been greatly intensified with regard to the results, and to the damage done, in consequence of fire resulting after the occurrence. This is greatly minimised by the use of electricity.

The cost of lighting by oil lamps may be put at ½d. per hour per lamp. Assuming a lamp to give about eight candle power, this would give a cost of .0615d. per candle power per hour. A compressed oil gas burner of eight candle power consuming .75 cubic feet of gas per hour would cost about .097 per lamp per hour, or .012 per candle power per hour. From particulars obtainable the cost of Stone's Electric Lighting is about 0.007 per candle power per hour; this includes interest on capital outlay.

The cost of equipping each coach with all plant and fittings necessary for electric lighting may be estimated at £195 per large bogie carriage. The cost of maintenance including renewal of lamps, plants, accumulators, belts, bearings, and other wearing parts for a coach burning for six hours per day is said to be about £11 per annum.

The first cost of electricity is greater, but it seems to be more free from possible dangers than either of the other systems. It has now advanced far beyond the point of experiment, and in Stone's system we have an arrangement for lighting coaches which can be absolutely depended upon.

In addition to the lighting of the vehicles, Stone's system can be made applicable to the cooling of coaches by the circulation of a current of cool air which very considerably reduces the temperature of the compartment.

---

### Acetylene and Oil Gas Lighting.

This system, while very convenient for small installations, is unsuitable for large ones, because the gas must be burnt practically as quickly as it is made. It is produced by the action of water on calcium carbide, but is soluble in water and cannot be stored long in

a holder. It is difficult, therefore, to provide a reserve for occasions when an exceptional number of lights are required. Another objection is the difficulty and cost of shipment of calcium carbide to the Colonies: the regular lines nearly always refuse to accept it at all.

Oil gas can be made from any oil, mineral, animal, or vegetable, and can be stored for any period. It is suitable for cooking, heating and driving gas engines, and the cost is low. At certain railway stations the cost of oil, fuel, and renewals comes to about 7d. per light for one hour. An apparatus providing for 30 lights consuming 1 cubic foot each for five hours burning (gasholder, 5 ft. 9 in. diameter, 6ft. depth), can be obtained for £72.

---

### National Air Gas System of Lighting.

This system has been installed at the new buildings of the War Office, but we understand that the department is not yet in a position to report on the result. The apparatus consists mainly of a hot-air engine, an air-blower, a vertical cylinder containing the supply of petrol, and a carburettor connecting by a service of pipes and valves to a small gas holder, the whole being self-contained and working automatically. It is claimed that the mixture of air and petrol is kept uniform, and that the variations of temperature are provided for. The flame produced, which is intensely hot, has of itself no illuminating power and is only combustible with special burners. In an office in Victoria Street, a 60-light apparatus is placed in a wooden shed outside the building, occupying a floor space of about 4 ft. by 2 ft. 6 ins. The main gas pipe from the engine is carried underground to the inside of the building direct to the burners in the lamps. To start this engine it is necessary to operate it by hand by turning the fly-wheel until a sufficient quantity of gas is made to light the burners under the cylinder which heats the air for working the cylinder, and it has to work for about 45 minutes before sufficient gas is made for lighting the building. The engine uses a gallon of petrol a day for the 60-lights. The plant gives no trouble and requires little attention. A very heavy low-grade petroleum spirit is found good enough, at a price of 5½d. per gallon in London: it is usually shipped from America. The system will probably be found convenient and cheap in many colonies. The price of the plant is from £45 upwards.

---

The West India Committee Circular contains a very hopeful account of the development of oil-boring in Trinidad, from which we extract the following:—

“Mr. A. Beeby Thompson, the well-known petroleum mining expert, who has just returned from a visit to Trinidad, speaks with

enthusiasm of the prospects of the petroleum industry in that colony. It has now passed the experimental stage, and active developments on a large scale may be anticipated in the near future. The Trinidad Petroleum Company, whose operations are centred at Guapo, have struck oil in all their recent wells in considerable quantities, and great quantities of gas accompany the oil. Some of the wells have flowed periodically, the oil gushing to a height of over 100 ft. One feature of great importance is the absence of water in the oil-bearing strata, which thus removes one of the worst difficulties so often to be met with in oil-field development. The petroleum of the Guapo district is of excellent quality, yielding on distillation a large percentage of illuminating and intermediate oils, as well as petrol and lubricating oils. The early difficulties of drilling, which much delayed the prospecting operations, have been entirely overcome by a combination form of rig designed to suit the local conditions, and wells can now be drilled at a much quicker rate than formerly. In the vicinity of the Pitch Lake at La Brea, six miles from the Guapo oil fields of the Trinidad Petroleum Company, several highly productive wells have been completed by the New Trinidad Lake Asphalt Company, and preparations are in progress for an increased scale of development. One well in April and May flowed continuously for about three weeks at an estimated rate of from 20 to 30 tons daily. The oil is of a heavy asphaltic description, specially suitable for fuel oil. Both the Trinidad Petroleum Company and the New Trinidad Lake Asphalt Company are using oil fuel in their boilers, and already arrangements are under consideration for supplying the electric power station in Port of Spain and other works with liquid fuel. The operated properties adjoin the coast and occur in the Gulf of Paria, where shipping is always protected, so that exceptional facilities exist for the cheap shipment of oil for export. There is no important oil field in the world so favourably located for the cheap disposal of the produced products to the markets of the world."

---

### Aluminium Wire.

The manufacture of aluminium has been growing steadily in the last few years. The cost has decreased, and in consequence it is being used to a considerable extent in America and on the Continent for overhead power transmission lines, and we believe that it has been erected in France for telegraph purposes.

In any comparison between the values of different metals for telegraphic line wire purposes, emphasis must be laid primarily on the fact that the wire which has the higher breaking strain is likely to give most satisfaction unless other characteristics are distinctly detrimental.

A copper wire with a diameter of  $\cdot 116''$  weighs 200 lbs. per mile ; has a resistance of 4.39 ohms per mile ; a breaking strain of 650 lbs, and costs at present market prices approximately £75 per ton. An aluminium wire with a diameter of  $\cdot 160''$  weighs 124 lbs. per mile ; has a resistance of 3.5 ohms per mile ; costs approximately £88 per ton, but has a breaking strain of only 620 lbs. On the other hand a three-ply stranded aluminium conductor, each wire having a diameter of  $\cdot 092''$ , weighs 126 lbs. per mile ; has a resistance of 3.54 ohms ; costs approximately £98 per ton, and has a breaking strain of 660 lbs.

Taking for comparison a line 100 miles long, with the above wires and present market prices, the copper wire would weigh 9 tons and cost £675 ; the aluminium wire—if solid—would weigh 5.6 tons and cost £493 ; if stranded, would weigh 5.7 tons and cost £550, so that with the solid aluminium conductor there would be, as compared with copper wire, a saving of £182 in cost, a reduction of 3.4 tons in weight, a reduction of 89 ohms in resistance, but also a reduction of 30 lbs. in tensile strength.

With the stranded conductor there would be, as compared with the copper wire, a saving in cost of £125, in weight a reduction of 3.3 tons, in resistance a reduction 85 ohms, and a slight increase in tensile strength.

Similarly a copper wire, weighing 150 lbs. per mile, could be replaced by a stranded aluminium wire, weighing 96 lbs. per mile (each strand having a diameter of  $\cdot 080''$ ), of identical breaking strain ; and with the 100 mile line, the resistance would be reduced 110 ohms. There would be a saving of 2.4 tons in weight, and a saving of £83 in cost.

The chief difficulty arising with the use of aluminium wire has been the making of a satisfactory joint. So far, soldered joints are not found reliable, owing to the impossibility of getting a good flux for this metal, and welded joints show decided reduction in the tensile strength at the joints. But it is now generally found that a joint made with the "Macintyre" sleeve gives complete satisfaction. This joint is made by means of a sleeve or tube into which the two ends of the wires to be connected are placed, a special tool is then used to twist the sleeve and the contained ends round. The result is a good electrical contact throughout between the wires and the sleeves, full tensile strength is maintained, and experience shows that no corrosion sets up and no extra resistance is added to the line.

For inland positions there is no doubt as to the utility of aluminium wire, but it is not certain whether it will stand the moist saline atmosphere on the sea coast.

### Internal Combustion Machines.

The use of internal combustion engines for marine purposes is being much discussed, and there are some clear advantages in it which are very important in the Colonies. A gas engine uses less than one-half the coal required by a steam plant, and the cost of stoking is not only so much lighter but is also easier, as the men are not exposed to the glare of the heat during the cleaning of the fires. The stokehold is cooler and cleaner. It is claimed that the pipes would be safer than those under high pressure of steam, and no doubt they would usually be much less troublesome, but there are dangers in a gas-pipe system. In small vessels, where there is little space, the internal combustion engine is the most suitable on these grounds. The drawbacks are the difficulty of varying the speed and of reversing, and in these respects it is very desirable that improvements in the machinery may be effected.

---

### Wireless Telegraphy.

The utility of wireless telegraphy on ships was dramatically illustrated in the rescue of the passengers and crew of the White Star liner "Republic" and again more recently in the case of the wreck of the "Slavonia." Some 180 steamers have been fitted with the Marconi equipment, about 150 being on the North Atlantic, and the system is being rapidly extended to the Mediterranean, South African, and South American routes. Messrs. Rennie, Son & Co. have set the example on the South African journey, and the Orient Co. propose to equip the five 12,000-ton steamers which they are building for the purposes of the Australian mail contract. Most of the vessels are fitted with an apparatus which only commands a distance of about 200 miles, but a long distance apparatus is coming into use, and, having regard to improvements and cheapening which are being effected, it is certain that the large ships of the near future will as a class be in touch with the world throughout their voyages.

---

### Rubber Growing.

Mr. John Ferguson, in his admirable paper read before the Royal Society of Arts, prophesied that the rubber crops in Ceylon would in five years hence yield £3,000,000 yearly. Some remarkable results are being achieved, and not the least satisfactory feature is that a small area and moderate capital can give excellent returns. One company with an issued capital of £6,000, possessing only 20 acres in bearing and 26 of young rubber, has in its second year paid a dividend of 21 per cent. An individual planter in the Perak district, holding 100 acres, netted an income in 1907 of £3,500. Single trees have given in a few months twelve to twenty pounds of rubber, worth over 5s. per pound, and small areas have given returns equal to more than £60 per acre profit in one year. The

average figures are of course less, but there can be little doubt that such land as that in Malaya, yielding mature rubber, gives the highest financial results of any agricultural land in the world.

---

### Steel Rails.

Some perturbation of mind has been caused by the fact that a large order has been placed in Russia for steel rails by the Cape Government. There is no getting over the fact that Russian rails are several shillings per ton cheaper than those procurable in this country, and we fear that purchases of them on colonial account would be more frequent than they are if shipments could be effected as conveniently from the Black Sea as from the United Kingdom. Prices in this country indicate the existence of a ring, and the export trade suffers accordingly.

---

### Spray Disinfector, Mark II.

A number of spray disinfectors are in use, but they have not given general satisfaction, and they have been superseded in the War Office service by the above, which is considered more efficient and is about one-third the usual price. It was devised by Dr. L. Mackenzie, Inspector of the Local Government Board, Scotland, and consists of a bucket, pump, suction tube, spray, crosspiece with two nozzles, additional rods for reaching ceiling, and rubber (or for hot climates) flexible metallic tubing. It is said that an ordinary room can be disinfected in ten minutes. The price, packed for shipment, is £2. 5s. 6d.

---

### Dust Preventive Compounds.

Dust is a terrible nuisance in many tropical places, especially where, as often happens, the roads are metalled with limestone. But unfortunately the preventive compounds are probably affected by the heat in a manner to which they are not subjected in more temperate climates, and they are also subjected to more violent rain storms. Tar is the best preventive known, but it is affected by great heat, even if properly refined by distillation. There are about twenty preparations on the market, but we have no information as yet as to their suitability for hot climates. A trial might be made of "Calcium chloride," "Clare's patent tar compo," "Lahnite," "Akonia," and "Tarvia," may also be picked out as likely preparations. The cost in this country varies from ½d. to 1d. per square yard.

---

### Sewage Schemes.

The Shone system has been tried and found very satisfactory at Rangoon. The annual cost of the complete scheme for a population of 75,243 was put at Rs. 1,79,158 (including interest on capital

cost and sinking fund). Experience with those parts of the town at present unsewered goes to show that collecting night-soil by pails is as costly as the sewerage system, and of course much less efficient, especially as the sulliage waters are not collected at all and seriously pollute the soil.

---

### Condensed Milk.

At the request of the Government of British Guiana a report has been obtained from Mr. F. J. Lloyd, F.I.C., as to the best brand of condensed milk for hospital use. Mr. Lloyd recommends the milks supplied by Messrs. Nestlé and the Anglo-Swiss Condensed Milk Co. He advises that it should be a condition for the milk to be homogenised as well as sterilised, and that the word "preserved" should not be used in ordering as it is most undesirable that the milk should contain any preservative.

---

### Motor Cars.

In hot climates large radiators are indispensable, as without them the engine is very likely to overheat and possibly seize. If the car is required for country without roads, such as the South African Veldt, quite a foot clearance from the ground is necessary, or there will be a great risk of collision with a high patch of ground. On ordinary roads this is not necessary, but as bumpy bits are frequently encountered the springs and axles should be specially strong.

A considerable number of cars for travelling and commercial purposes have been supplied for the Crown Colonies by the Lacre Motor Car Co.

---

### Gold Coast Harbour Works.

During the construction of the breakwater, a deposit of sand has taken place within the sheltered area of the harbour, and under such circumstances, when the sand is of a light character, freely carried in suspension in disturbed water, but deposited in sheltered water, the best course is to use a centrifugal sand-pump, with engine, boiler, and the necessary suction and delivery piping. A suitable timber platform should be erected in anticipation of the arrival of the machinery.

It is now proposed that the breakwater, which as originally projected was to be 800 feet long, shall be extended to a further distance of 250 feet, and that the jetty under its lee should be extended from 270 feet by a further 150 feet. These works would, it is expected, be accomplished by the end of 1910. These plans would cause the postponement of the block-setting in the projected breakwater at Sekondi till September, 1910, as the plant at Accra will be required for this work.

## RAILWAY NOTES.

### South African Railways.

A clear and instructive report on these railways has been written by Mr. F. Bedford Glasier, General Manager of the Lagos Railway, as the result of a tour of inspection. The lines have the enormous advantage of cheap coal. The average price paid by the Central South African Railways is under 6s. a ton of 2,000 lbs; this averages 2½d. per engine mile. But this is far from being sufficient to make lines pay which have been built from political or rather local policy and which could not be expected to be remunerative. If a Government deliberately constructs a railway to develop a particular district or industry, the policy may be perfectly legitimate, but the financial results should be clearly shown. There is a great temptation not to do this, but to grant special rates for a particular branch, and to cover up the result by including the accounts in those of the whole system. The general rates have therefore to suffer. If it is decided to encourage a particular district, the cost of doing so should be shown and met openly by a definite grant in aid. The necessity of meeting the situation in this way would no doubt militate strongly against the adoption of inconsiderate schemes. That the mischief is a very real one is shown by the fact that in Australia some lines have been actually closed for traffic, and that there is now talk of closing the main line north of the Victoria Falls. In Australia the abuse was stopped by vesting the control in commissioners who are free from political influences. India is an example of the proper application of business principles.

---

### Natal.

In 1908 the revenue came to £1,832,862, a decrease of £4,842, and the working expenditure to £1,240,319, a decrease of £27,824. The heavy loss in commercial seaborne traffic to the Transvaal and Orange River Colony has continued. Coal traffic has kept up the

marked development which commenced in the middle of 1907, the tonnage being 1,571,919. There has also been a very decided increase in the local sugar production, the tonnage landed being 35·6 per cent. in excess of 1907. Apart from sugar the agricultural development of the country has been retarded by the continued spread of East Coast Cattle fever, and it is much to be hoped that the union of South Africa will cause these plagues to be dealt with more effectually. The maize export, however, was larger and the prices good: in the present year a record crop is probable unless the unforeseen happens. Five Hendric D. Goods type engines were ordered in this country, and 50 thirty-five tons capacity wagons were obtained from the Leeds Forge Company, but a trial is to be made of the construction of wagons locally. In recent years the cast iron chairs have been replaced by steel chairs and buttresses, and they have proved such a success that enquiries have been received from other places, including the United States, where in some cases the wear on the rails and wheel flanges is abnormal. Experiments are being made with a small number of reinforced concrete sleepers, which are being used largely in America and Italy, but their weight and cost make difficulties. The expenditure of the Maintenance Department was £195 per open mile.

---

### Ceylon.

Mr. John Ferguson read an excellent paper on 6th April to the Royal Society of Arts, in the course of which he commented on certain railway extensions which have been strongly urged, but not yet agreed to. Mr. Ferguson's arguments were fairly and moderately put, and he did not resort to the common device of accusing the Colonial Office of apathy or lethargy, because it has to undertake the invidious role of closely scrutinising all proposals for large expenditure. The accepted proposals in 1908 included, besides railway works, such heavy items as the drainage of Colombo, survey, Colombo Lake development, irrigation, water supply, and so forth. These special works were estimated to come to Rs. 50,414,000 chargeable to loan, and Rs. 16,905,634 chargeable to surplus balances. The programme of public works is a long and miscellaneous one, and involves an expenditure largely in excess of any sum suggested in the preceding correspondence. The island is, however, so thriving that great expectations may be formed of its development, and the full discussion of these questions cannot but be helpful.

---

### Nigeria.

The correspondence which has been published relating to railway construction in Nigeria (Cd. 4523) is of unusual interest. It discloses the arguments which were employed for two separate and

to some extent competing schemes, and incidentally lifts the curtain which usually screens the combats of Government offices from the public eye by setting out the correspondence with the Treasury. Ultimately it was arranged that the loan required for the Baro-Kano railway should be raised by Southern Nigeria, but that that colony should be relieved of interest charges as they accrue from year to year, by remitting equivalent sums from her annual contribution to Northern Nigeria. Thus the two provinces are treated as practically one for this purpose, and no doubt, eventually, they will be amalgamated.

The adoption of both of the Nigerian schemes, the Lagos extension and the Baro-Kano, does not close the discussion of their comparative merits and of the future administration. The latter line can only be made effective, independently of Lagos, by improving the navigation of the Niger, but objection is taken to the expenditure of large sums for this purpose. This argument is put vigorously by Sir Walter Egerton as follows:—

“Can it be doubted that, given a direct line to the important centres of Zaria and Kano, the history of the Mississippi will be repeated on the Niger? The railway will give a daily service to and from all the chief producing centres, and, as traffic increases, at much lower rates for long distances, with the added advantage that Lagos by the time the railway reaches Kano, if the harbour works are persevered with, will be a commodious harbour, safe for the largest West African steamers and well equipped with wharves and all the facilities for quickly loading and discharging ocean steamers. Those familiar with shipping and commercial matters know what an advantage such a port must have over a port like Forcados, and ocean freights must drop where the traffic increases in volume and approved facilities for dealing with it are furnished.

“I would urge upon your Lordship that, although there may be justification for building the Baro line to meet local requirements, there is no justification for in any way sacrificing the interest of the more important Lagos-hinterland line in order to give slightly better communication between Baro and Kano.

“The above is written purely from a consideration of commercial advantage; but from an administrative or strategical standpoint the arguments are almost equally strong in favour of the Lagos line, for, comparing Nigeria with India, Lagos is the Calcutta and Zaria can never be more than the chief administrative station in the interior, or its Simla.

“The Niger River will always be an important commercial trade route, but, like the Mississippi, only for the local trade to places on or adjacent to the river system, provided Government does not interfere to prevent trade taking its natural route.

“ It may be admitted that in the United States one of the chief reasons for the Government spending large sums in improving the navigation of the magnificent Mississippi waterway is to prevent the powerful railway trusts unduly raising freights on railway-borne goods so that it may not be possible for any combination of railway magnates to raise freights on the railways, because, if they do, the traffic can be diverted to the river. In Nigeria no such reason for expenditure, ‘ which would not be justified from purely commercial considerations alone,’ exists, because the railway belongs to the Government and the Government controls its rates.

“ I do not know what expenditure in dredging on the Niger is contemplated, but the annual expenditure can hardly be reduced below £5,000 a year. The present traffic on the river passing Idah was in 1907 only about 20,000 tons, inclusive of railway materials. If an expenditure of £60,000 a year on the Mississippi with the traffic of 2,306,362 tons in 1901 when dredging was commenced (or of 1,719,893 tons in 1906) is not justified commercially, is an expenditure of £5,000 justified on the Niger with a traffic of 20,000 tons. ?

“ I do not wish to appear as an opponent to the dredging of the Niger, but what I do wish to urge is that the Baro-Kano line should be considered as a branch line and that the Lagos-Kano line should be constructed as the main line on the route which is best from Lagos to Kano and not on the route that may give a better line from Baro to Kano. Taking the Lagos line from Zungeru to the alignment proposed for the Baro-Kano line means, probably, an addition of over 30 miles to its length, for by this route on leaving Zungeru it does not begin to advance towards Zaria until after joining the Baro alignment.”

Dredging, however, may be thoroughly justified if it leads to a considerable traffic, and in the case of heavy and bulky goods, there is a reasonable expectation that the river will secure a good share of the through freight. It is true that there is not, and probably never will be, a harbour at the mouth of the Niger, but this is immaterial so long as goods can be easily transhipped there.

Messrs. Elder, Dempster & Co., have signed an agreement for carrying up the railway material this year, and the new boat “ Uromi,” carrying at least 1,000 tons, will be in time for the July working.

---

### Jebba Train Ferry.

A steamship of unique type has been built by Messrs. Rennie & Co., Greenwich, to act as a train ferry at Jebba on the Niger. It is of double-ended type, and has a balance rudder at each end. It will carry six wagons or passenger carriages of 24 tons

each : there are two lines of rails running over the whole length of the deck, and at each end there is a hinged prow, raised and lowered by counter-balance weights. The hull is of Siemens-Martin steel, galvanized throughout, and woodwork is of teak. A large water ballast tank is provided to regulate the height, and this is divided into seven compartments, so that any trim can be given to the vessel. A noticeable feature is the arrangement by which the capstans can be sunk out of the way to the level of the deck. The ferry is a paddle boat, 160 ft. long by 33 ft. 6 ins. beam ; the displacement, fully loaded, 560 tons ; draught, 5 ft. 6 ins. ; speed,  $7\frac{1}{2}$  knots : contract price, £13,588. The ferry boat will eventually be displaced by a bridge over the southern branch of the Niger. The bridge over the northern branch (between 400 and 500 feet in length) is under construction.

---

### Sierra Leone.

For nearly the whole of 1907 the price of palm kernels and palm oil was abnormally high, but towards the end of the year it fell, and a really better state of business was not evident till September, 1908. The railway is greatly affected by these variations, and during the first half of 1908 a drop in the receipts occurred. Since December, 1908, however, the traffic has greatly improved.

---

### Trinidad.

Extensions are contemplated of the railway system to Rio Clara and Siparia, at an estimated cost of £8,247 and £8,791 a mile. The total cost of the scheme is put at £371,979, and in due course a loan will be issued to meet it.

---

### Hong Kong.

A very complete review of railway undertakings in China was given by Mr. A. J. Barry, M.I.C.E., before the Royal Society of Arts, on 19th May. He referred to the Canton-Kowloon Railway as follows :—

“The Canton-Kowloon Railway is a very important line, 100 miles in length. It starts at Canton, the great commercial centre of South China, and terminates at the frontier of the British leased territory of Kowloon by a junction with a very expensive and heavy section of railway 20 miles long that the Hong Kong colony are constructing to complete the connection between Hong Kong and Canton. In the future, if all goes well, by means of this railway Hong Kong and Canton will be put in direct railway communication with Hankow, the future Clapham Junction of the great trunk lines of China, and thence with Peking itself, so that before many

years it should be possible to take a railway ticket at Victoria Station to Hong Kong *via* Berlin, Moscow, Siberia, Peking, and Hankow.

“The amount of the loan is £1,500,000, and, although rather serious delays in getting possession of the necessary land have involved unnecessary expenditure, the railway is likely to be completed for the amount of the loan, or at any rate very nearly so.”

The history of these undertakings is one of steadily increasing control by the Chinese Government. This movement had advanced considerably at the time of the Canton-Kowloon agreement; provision was made for a Chinese managing director, and the chief engineer nominated by the bondholders is subject to the approval of the Chinese. In subsequent schemes the Chinese have claimed the right of appointing the chief engineer, and their demands may act as a check to further enterprise; but in the Kowloon-Canton case the Chinese director and his British assistants have been on excellent terms with one another.

---

#### **Johannesburg to Buluwayo.**

Mr. Smuts, Mr. Hull, and Sir T. Price have paid a visit to Trichardt to consider on the spot the project of extending the railway from Pietersburg to Rhodesia. It is understood that the project is favourably regarded. Such a line would greatly improve Rhodesia's communications, and there should be an exchange of commodities which would be highly valuable to both communities.

---

#### **Accra—Akwapim.**

The first sod for this line was cut by Sir John Rodger on 7th January, and the funds will be provided out of the loan recently issued. The line authorised is for 40 miles, but it is hoped that it will be at no distant date extended to Coomassi. It is for agricultural purposes, and promises not merely to cheapen transport but to give a great impetus to the process under which the natives are becoming agriculturists. The phenomenal expansion of the cocoa industry bears witness to the capacity of the natives for husbandry, and not the least gain from the undertaking will be the complete conversion of the till lately ferocious Ashantis into industrious tillers of the soil.

---

#### **Bridges.**

Many bridges in the East are built of teak, but it is found that the life of a piece of teak does not exceed 15 years and is sometimes not more than ten. A cubic foot of teak, including all the processes, costs from six to seven rupees to repair. One bridge, 533 feet long, costs in annual repairs 4,000 rupees. In such cases it

is desirable to replace the timber with reinforced concrete, and the cost is comparatively small, being often less than that of the annual repairs. A very satisfactory mixture for concrete has been made of broken basalt stone from  $1\frac{1}{2}$  to  $\frac{1}{2}$  inch nine parts, screened coral sand six parts, Portland cement (which should be good) three parts. After the concrete has been laid, it should be kept moist and protected from the heat, to permit an even setting. One advantage of reinforced concrete over steel is that the cost of painting is saved.

---

### Sleepers.

It has been found on the Rhodesian railways that no wood sleeper is absolutely secure from white ants; even a creosoted Baltic will eventually succumb, as long before it would otherwise succumb it loses its objectionable taste to them. An order which was given for native hard wood, to encourage local industry, turned out unfortunately; the wood was very heavy, split easily, and warped very badly. Both Karri and Jarrah have failed. Steel sleepers used since 1892, on the other hand, are apparently little the worse for wear.

## MEDICAL NOTES.

### Sanitation in the Colonies.

SIR RUBERT BOYCE, who has visited the West Indies on behalf of the Colonial Office, has found evidences of sanitary progress all along the line. It is reported that Barbados is issuing summonses on an extensive scale against those persons who harbour mosquito larvæ on their premises—an extension of the laws against harbouring which certainly shows a determination to deal drastically with the mischief. All along the islands, Sir Rubert states, the authorities are flocking to the standard of hygienic reform. In particular he mentions the very genuine endeavour made to improve the health conditions of the indentured labour on the sugar cane estates.

A very different note was sounded by Major Ronald Ross before the Royal Institution. He summed up the work done in the words "very little." Speaking of the colonial reports published in the Report of the Advisory Committee of the Tropical Diseases Research Fund for 1907, he stated that "Only those furnished by seven colonies, namely, Southern Rhodesia, Papua, Mauritius, British Central Africa, Gambia, Ceylon, and Southern Nigeria, showed evidence of any real interest in the matter. Those from Bahamas, Barbados, Jamaica, and St. Kitts-Nevis showed, to my mind, nothing but neglect of public duty, while those from Northern Nigeria, St. Lucia, British Honduras, Grenada, Somaliland, Straits Settlements, and Sierra Leone gave no decisive evidence of the result."

Major Ross puts the blame mostly on the shoulders of the heads of the medical departments. "Worse heads of departments cannot be found. They scoff at the knowledge and efforts of others in order to cover their own ignorance and apathy. To them all new discoveries are frauds, and all new proposals are charlatanism. They repress every kind of honest endeavour among their juniors; they fill the best appointments with their own friends; and they truckle to their official superiors in the hope of obtaining further preferment. At last, decorated and pensioned, they leave the field to others of their own stamp—men without an idea or an ideal, except such as refer to their own advancement. These are the

persons who are really responsible for the state of things which I have described."

This is strong language, and with all deference to Major Ross we think it is undeserved. He appears to ignore the great practical difficulties in the way of sanitary reform in the Crown Colonies. The great obstacle to rapid progress is the ignorance and indifference of the public, which is nearly all coloured. Education is wanted, and this is a work of no little time. The practical administration cannot be expected to ride rough-shod over the popular feelings, however prejudiced or stupid they may be, and the chief medical officers have common sense enough to realise that the Government cannot instantly do a thing because it is scientifically right. Progress is undoubtedly being made, and the information given by Sir Rubert Boyce about the West Indies shows that that acted upon by Major Ross is more or less out of date. Still it is useful to have some pressure applied, and the zeal shown for the cause by Major Ross will not be wasted.

---

Further bulletins have been issued by the Sleeping Sickness Bureau. The principal articles in No. 5 are entitled "The Development of Trypanosomes in Tsetse-flies," "Mode of Transmission of Trypanosomes by Tsetse-flies," and "Report on Human Trypanosomiasis from Léopoldville." The sixth number contains an account of the important discovery by Professor Kleine, since confirmed by Sir David Bruce, that more than one species of tsetse-fly can transmit trypanosomiasis to animals, a fact which suggests the possibility of an analogous state of affairs in the case of human trypanosomiasis. In future issues of the bulletin it is proposed to pay greater attention to trypanosomiasis in animals. In this connection it may be noted that the Sleeping Sickness Commission of the Royal Society in Uganda, of which Sir David Bruce is in charge, has issued a report on an outbreak of disease among cattle on an estate belonging to the Uganda Company, in which a special appeal is made for information and assistance from all who are interested in stock-raising in the colony.

---

We reproduce below a letter which Sir Rubert Boyce has addressed to the Governor of Barbados on the subject of the recent occurrence of cases of Yellow Fever in the island.

" BARBADOS,

" *March 26th, 1909.*

" YOUR EXCELLENCY,

" In a letter, No. £058/1909, the Right Honourable the Earl of Crewe, Secretary of State for the Colonies, informed me that this

Colony desired the services of an expert to advise on the steps which should be taken to cope with the present outbreak of Yellow Fever and to guard against its recurrence. I gladly offered my services and arrived in this Colony on March 1st, and I beg to report briefly to your Excellency as follows, leaving to a subsequent date my full report, when, having ascertained additional facts I will be able to report more fully :—

“ NATURE OF DISEASE : WHETHER YELLOW FEVER OR NOT.

“ In company with Dr. Hutson and other Medical Officers I visited several supposed cases of Yellow Fever on my arrival, and had no difficulty in coming to the conclusion that they were cases of genuine Yellow Fever. I had also the advantage of making two post-mortem examinations which put all doubt at once at rest, and for the guidance of others I beg to repeat, as I did in my Honduranian report, that a post-mortem examination is the final proof of Yellow Fever, and that therefore a post-mortem examination should be held at the very first opportunity. The findings obtained from it are absolutely conclusive.

“ SIZE OF EPIDEMIC.

“ I satisfied myself that the epidemic was one of small dimensions, but that it was very scattered all over the Island and not concentrated in one particular focus. I am of opinion, however, that the epidemic would have been much larger had it not been for the scrupulous conscientiousness and vigilance of Dr. Hutson and many of his colleagues in various parishes, and for the energy displayed by the sanitary staff. I consider, however, that a very great deal of injury has been done and unnecessary weakening caused to the sanitary reputation of the Colony, as well as a great deal of suffering produced by an undoubted hostile feeling voiced in the press and elsewhere against early notification. All authorities upon Yellow Fever have emphasized the absolute necessity of early notification. It has been pointed out time and time again that prompt notification is the only way to avert commercial disaster, and that a community is exceedingly short-sighted if it does not exert itself to bring about early notification. Absolute honesty in this respect is the only basis upon which international and intercolonial quarantine measures can be carried out.

“ ANTI-YELLOW FEVER MEASURES IN FORCE.

“ I found on my arrival that the Health Authority was fully alive to the importance of vigorous action, and had framed and promulgated exceedingly wise anti-mosquito measures. I made it my

business to at once see how far these measures had been carried out, in other words to ascertain the strength of the defence of the Colony against Yellow Fever.

#### “ VISIT TO PARISHES.

“ For this purpose I visited all the parishes and had long interviews with the Parochial Medical Officers. I found, to my great satisfaction, evidence on all sides of the conscientious and vigorous action of the Parochial Sanitary Authorities. In many of the Parishes simple but exceedingly effective Yellow Fever hospitals had been erected, and I beg here to testify that in my opinion it has been this prompt action on the part of the Parochial Sanitary Authorities and their Medical Officers that has confined the epidemic to its small size in the straggling parishes of the island.

#### “ HOUSE TO HOUSE VISITS IN BRIDGETOWN AND STEGOMYIA.

##### SURVEY.

“ I instituted an early house to house inspection throughout Bridgetown and I have visited 525 houses and yards, and thoroughly inspected them from a sanitary and water supply point of view. The houses visited may be divided into three classes: (1) Those of the rich and well-to-do, (2) Those of the poor, and (3) Those of the very poor. With regard to the first category the fact that each house has a water supply laid on to it has done away with the necessity of water receptacles of any kind, and in consequence no breeding places of *stegomyia* larvæ were found. With regard to the second category, whilst a few of the houses had a water supply laid on, the majority employed numerous receptacles, chiefly barrels, and a large proportion of these were infected with *stegomyia* larvæ. On the other hand, the very poor had fewer receptacles and therefore a smaller percentage of *stegomyia* was found. At each house visited, I pointed out the danger of harbouring *stegomyia*, and I wish here to record my satisfaction of the way in which all classes of society have backed up my efforts, and the intelligent interest which even the very poorest have taken in getting rid of the pest. The total number of water receptacles examined was 993. RESULT: The *Stegomyia callopus* is the common house mosquito of Barbados and is still abundant, *i.e.*, in 11 per cent. of the houses, and must be got rid of before the island can be considered secure.

#### “ REMOVAL OF ODD RECEPTACLES.

“ During these house to house visits, in which I was accompanied by the Chairman of the Sanitary Commissioners, and the Sanitary Inspectors, and the dust contractors, an enormous number of odd

receptacles of all kinds were got rid of. This will mean that when the rainy and dangerous season commences there will be infinitely fewer breeding places for mosquitoes. I wish to record my thanks and appreciation of the loyal co-operation which I have received from the Medical Profession and the Sanitary Authorities of the Island, and above all for the courtesy and kindness which I have received at your Excellency's hands. It is you who have enabled me to rapidly instal an office and commence operations immediately upon my arrival, and you have enabled me further to meet all classes of the community. In conclusion, although it is useless to cry over spilt milk, I would be lacking in appreciation of the efforts of others did I not point out the warnings which have been raised from time to time in connection with Yellow Fever in this and other West Indian Islands. The Colonial Office, Dr. Low, Drs. Hutson, Bridger, and others, have shown the weak spot in the anti-Yellow Fever armour of the Island, namely, the fact that the Colony was harbouring and breeding the stegomyia mosquito. Since 1905 it has been emphasized throughout the civilised world that there is no necessity for the existence of yellow fever; that as it is a disease unlike small pox, scarlet fever, typhoid, and such like, it can readily be controlled and banished, because of the fact that there is only one agency at work in its propagation, and that is an agent which can with energy and little expenditure of money be completely got rid of. I therefore beg to recommend in this preliminary review of the situation that energetic Anti-Yellow Fever measures be continued not only in Bridgetown but in every part of the island, and for this reason: It is evident that owing to the very diffuse way in which yellow fever has spread over the island, there must still be remaining in the island, in the houses, a considerable number of adult affected infected Stegomyia, for it will be understood that this must be so, as there has not been a complete house to house fumigation in the island. Therefore these adult Stegas will, when an opportunity arrives, lay their eggs and perpetuate the species, and therefore I counsel no diminution at present in the sanitary staff, for we have still many hot months and the rainy season to encounter.

#### “STANDPIPES.

“A factor which has very greatly simplified the work of the authorities is the magnificent water supply in the Island. A few localities still remain where the stand-pipes are few and far between. I strongly recommend the increasing of these standpipes at the earliest possible opportunity. Such an action would do away with more and more the necessity for water receptacles.

“In conclusion I have much pleasure in expressing the opinion, from my own personal observation of the people and the sanitary

measures already adopted, with the meteorology and geological conditions of the island, that the problem of fighting Yellow Fever is a comparatively simple one, and I can assure you that with the conscientious carrying out of the well-recognised anti-mosquito measures, Yellow Fever will become a thing of the past and that never again need the commerce of the port be crippled and the poor made to suffer.

"It is not my purpose here to enter into the question of improvements in Sanitary Administration which I would like to see carried out for the better security of the Island. At the present time there exists undoubted evidence of lack of sanitary and medical organisation and co-ordination, but I foresee no difficulty in adjusting this without in any way interfering with the general sanitary policy of the Island.

"In conclusion I wish to thank the Colonial Secretary, Mr. Yearwood, Dr. Chandler and Dr. Hutson and the Chief Sanitary Inspectors for much assistance and advice.

"I also wish to tender my thanks to my Clerk and namesake, Mr. Boyce, who has very materially facilitated my work, and who has been most energetic, and painstaking, and tactful.

"I have the honour to be,

"Sir,

"Your most obedient Servant,

"RUBERT BOYCE."

---

### Vaccine Lymph.

Complaints are frequently made that lymph sent to hot countries is found to be inert. Dr. Alan Green, of the Lister Institute, has advised that calf lymph preparations containing glycerine or other germicides inevitably suffer in the potency of the lymph micro-organism when the preparation is exposed to a high temperature, and recommends a trial of dried powdered vaccine. It is thought that the specific organism when dried is probably in a resting stage, and is consequently less susceptible to the adverse influence of heat; one report on this lymph from West Africa supports this view.

---

We have received Vol. II., No. 5, of "*Annals of Tropical Medicine and Parasitology*," issued by the Liverpool School of Tropical Medicine. The place of honour is given to an article on "The Nomenclature of the Mammalian Trypanosomes observed in North-Western Rhodesia," by Doctors Montgomery and Kinghorn, and several other articles deal with different aspects of Trypanosomiasis. Doctor Marsden discusses native drugs in use in the Congo.

receptacles of all kinds were got rid of. This will mean that when the rainy and dangerous season commences there will be infinitely fewer breeding places for mosquitoes. I wish to record my thanks and appreciation of the loyal co-operation which I have received from the Medical Profession and the Sanitary Authorities of the Island, and above all for the courtesy and kindness which I have received at your Excellency's hands. It is you who have enabled me to rapidly instal an office and commence operations immediately upon my arrival, and you have enabled me further to meet all classes of the community. In conclusion, although it is useless to cry over spilt milk, I would be lacking in appreciation of the efforts of others did I not point out the warnings which have been raised from time to time in connection with Yellow Fever in this and other West Indian Islands. The place of honour is given to an article on "The Nomenclature of the Mammalian Trypanosomes observed in North-Western Rhodesia," by Doctors Montgomery and Kinghorn, and several other articles deal with different aspects of Trypanosomiasis. Doctor Marsden discusses native drugs in use in the Congo.

**Ratin.**

In our last number we referred to the failure of a trial of this preparation by the Cape Department of Public Health. We have received the following letter on the subject :

“SIR,

“I notice in your last issue a short paragraph dealing with the results obtained from the use of Ratin at Cape Town, and with your permission I should be glad to be allowed to give my view on this matter.

“The Cape Town Harbour Board sent an order through their London Agents for a supply of Ratin, and I told them that it was necessary, to obtain proper results from our preparation, that a fair quantity should be used, and that in order to deal with the rat plague at the Docks not less than 30 tins should be applied. These calculations were based upon the amount of Ratin we had used in dealing with the rat plague at Tilbury Docks, where the results had proved entirely satisfactory. I further stated that it would be necessary to continue the treatment, because rats are always likely to return, and it is quite as important to prevent them from returning as it is to exterminate them, so that once a campaign has been started it should be followed up.

“In spite of this advice, the Agents in London only ordered two tins, which were sent out to the Cape, and part of one tin was used on caged rats, the other lot, as far as I know, was applied in the Docks without apparent results.

“This in my opinion is not fair to us, because too small a quantity was used altogether to form any idea of our preparation. Where you are dealing with matter containing living organism every fair minded man will agree that to take one tin and judge the rest from this is entirely wrong and, further, as regards the other tin, which was used in the Docks, I feel certain that the people did not follow the treatment thoroughly, and they thought because they saw no dead rats that the results were negative.

“Now I have the authority of the following officials who state that Ratin does kill rats and sets up a disease amongst them, and I may say that most of these officials have used it on a very extensive scale :—

The Minister of Agriculture, Quebec.

The Minister of Public Works, Cairo.

The Governor, Falkland Islands.

The Colonial Secretary, Grenada.

The Surgeon-General, Georgetown, Demerara.

The Medical Officer of Health, Khargpur, who twice tested Ratin on a very extensive scale on behalf of the Bengal-Nagpur Railway.

"In view of this I feel sure that we have in Ratin a preparation which deserves to be widely known, and more particularly now when our Dr. Bahr has been able to put up the Tropical Ratin, and which we are now having such a considerable demand for from the tropics. This preparation is the result of very extensive researches made for the last two years by Dr. Bahr, and he feels that he has now found the very thing that will deal with the rat trouble in hot climates, and no one who understands the danger of rats in the tropics will undervalue the great importance of such a discovery.

"I am, Sir,

"Your obedient Servant,

"The Ratin Laboratory,"

"C. A. BURN, Manager."

## COLONIAL STAMPS.

WE have received a copy of *Gibbons' Stamp Weekly* of 24th April, containing an article on the Cayman Islands case, referred to in our last number. The writer has evidently gone carefully into the matter, and it would require more knowledge of the circumstances than we possess to discuss the points with him. As regards the connection of Messrs. Whitfield, King & Co. with the affair, it is clear that there is no imputation against them, and the moral of the case is that there are strong objections to all "provisionals."

We have received some complaints from dealers in this country that comparatively large orders for new Colonial issues have in certain cases not been complied with, though small orders have. Presumably the local postmaster has been afraid of having his stock depleted by these large orders and prefers to satisfy the small demands. Possibly also he has a feeling against sending supplies for purposes which are obviously philatelic and not postal. Governments, however, are by no means averse to taking the profit derived from collectors, and it may be as well to point out that if the large dealers are discouraged in this way from getting supplies the business will probably be seriously diminished. The demand for a new issue from this quarter can be roughly estimated and allowance made for it in fixing the quantity to be printed.

ANTIGUA.—1d. stamps entirely red are about to be despatched.

BARBADOS has adopted the new colour scheme, and  $\frac{1}{2}$ d., 1d. and 6d. stamps have been supplied, all on unsurfaced paper.

BERMUDA.—A supply of  $2\frac{1}{2}$ d. stamps, entirely in blue, is about to be sent out.

DOMINICA.—In applying the new colour scheme, it has been thought advisable to reverse the colours in which the centre and border are printed, in order that the larger portion of the stamp may be in the doubly fugitive colour. New 2d., 3d. and 6d. stamps have been supplied, but the reversal of the colours is not very perceptible in the case of these values, as the appearance presented is practically that of a single colour stamp.

EAST AFRICA.—Rs. 2 stamps, printed on multiple watermarked paper, are about to be shipped.

GAMBIA has decided to adopt the new colour scheme, but not to apply it to the 5d., 7½d., 10d., 1s. 6d. and 3s. values which will be in the following colours:—

5d.	same as the existing	2d. stamp.
7½d.	”	”
10d.	”	”
1s. 6d.	”	”
3s.	bright yellow with bright green overprint.	

Stamps of all values are on order.

LEEWARD ISLANDS.—A supply of new ¼d. stamps of the existing design are on the point of being despatched.

NATAL.—3d., 4d. and 5d. Postage and Revenue stamps will in future follow the new colour scheme and be printed partly in doubly fugitive ink, and therefore on surfaced paper.

The only Natal stamps concerning the colour of which no change has been announced are the 1½d. and 2d. values.

SOUTHERN NIGERIA.—A supply of 2d., 3d., 4d., 6d., 1s., 2s. 6d., 5s. and 10s. stamps in the new colours has been sent out.

ST. LUCIA.—A supply of 3d. and 1s. stamps in the new colours have been despatched.

ST. VINCENT.—The 2d. stamp will, when next required, be printed in accordance with the new colour scheme, entirely in grey.

The stop under the “d” representing “pence,” which has been omitted in the case of the revised 1d. and 6d. stamps, will be inserted in all future printings.

SIERRA LEONE.—2d., 3d., 4d., 5d. and 1s. stamps of the new colours have been supplied. Also 6d. stamps for the first time on surfaced paper.

TRANSVAAL.—The next issue of 6d. Postage and Revenue stamps will be in singly fugitive ink on unsurfaced paper, and that of £1 postage stamps in doubly fugitive ink on surfaced paper. Stamps of both sorts are in course of manufacture and the colours will not be materially changed. 2d. stamps are also on order, printed entirely in grey.

TURKS ISLANDS are preparing to issue a set of stamps of a type similar to those of the Falkland Islands. The colours will follow the new colour scheme, except in the case of the following:—

- 4d. red on yellow paper.
- 2s. red on green paper.
- 3s. black on red paper.

The stamps will thus each be printed in one colour by the copper-plate process. The paper will therefore be unsurfaced.

TRINIDAD.—In order to comply with the Postal Union requirements, new plates have been ordered for the  $\frac{1}{2}$ d., 1d., and 2 $\frac{1}{2}$ d. values, showing the duties in Arabic numerals. A supply of stamps from the new plates has been requisitioned, and also of 4d., 6d., and 1s. stamps in the new colours. The last named have been despatched.

Since our last issue three more of Mr. Melville's little monographs have reached us, the subjects being "United States 1847-1869," "Gambia," and "Nevis." They certainly seem to merit no less praise than the previous volumes.

Stanley Gibbons' "Annual Priced Catalogue for 1909," in two volumes, published at 391, Strand, W.C., has made its appearance:—

"Priced Catalogue of Stamps of the British Empire, 1909."

2s. 6d. net.

"Priced Catalogue of Stamps of Foreign Countries, 1909."

2s. 6d. net.

## RECENT TRANSFERS AND PROMOTIONS MADE BY THE SECRETARY OF STATE.

- Mr. E. BLACKWOOD WRIGHT (Chief Justice of Seyohelles), Stipendiary Magistrate, Port of Spain, Trinidad.
- Mr. A. K. YOUNG (Stipendiary Magistrate, Port of Spain, Trinidad), Chief Justice of Seyohelles.
- Mr. R. S. JOHNSTONE (Stipendiary Magistrate, Bahamas), Chief Justice of Grenada.
- Mr. W. L. MCKINSTRY (Officer of Customs, Barbados), Treasurer and Collector of Customs, British Honduras.
- Mr. J. B. CARRUTHERS (Director of Agriculture and Government Botanist, Federated Malay States), Government Botanist and Assistant Director of Agriculture, Trinidad.
- Mr. N. C. McLEOD (Deputy Conservator of Forests, Southern Nigeria), Conservator of Forests, Gold Coast.
- Dr. R. S. EARL (Commissioner and Medical Officer, Virgin Islands), Colonial Surgeon, Falkland Islands.
- Dr. A. E. IRELAND (Government Medical Officer, GrandTurks), Medical Officer of Health, Fiji.
- Dr. T. R. ROBERTSON (District Commissioner and Medical Officer, Caicos Islands), Government Medical Officer, Grand Turks.
- Mr. E. A. HANCOCK (formerly Head Master of St. Kitts Grammar School), Assistant Master, Queen's Royal College, Trinidad.
- Mr. T. E. KEWLEY (Traffic Officer, Sierra Leone Railway), Deputy Assistant Traffic Manager, Baro Kano Railway, Northern Nigeria.
- Mr. J. D. BATHGATE (retrenched from Transvaal Civil Service), Engineer, Public Works Department, Southern Nigeria.

- Mr. H. C. HUGGINS (Draughtsman and Estimator, Public Works Department, Trinidad), Engineer, Public Works Department, Southern Nigeria.
- Mr. J. M. LUMLEY (retrenched from South African Constabulary), District Superintendent of Police, East African Protectorate.
- Mr. G. B. ANDERSON (retrenched from Transvaal Civil Service), Clerk in Public Works Department, Nyasaland.
- Mr. W. S. AKERS (late Clerk, Central South African Railways), Relief Clerk, Land Office, East African Protectorate.
- Captain W. E. BEAMISH (late Lieutenant, Southern Nigeria Regiment, West African Frontier Force), Assistant District Commissioner, Southern Nigeria.
- Mr. F. W. GARVEY (retrenched from Transvaal Town Police), Assistant Commissioner of Police, Southern Nigeria.
- Mr. F. S. GRANT (late of South African Constabulary), Inspector, Federated Malay States Police.
- Mr. J. M. SKIRVING (Inspector of Police, St. Helena), Inspector of Police, Antigua.

## OFFICIALS ON LEAVE OF ABSENCE IN THIS COUNTRY WITH DATE OF EXPIRATION OF LEAVE.

THE  
COLONIAL OFFICE  
JOURNAL.

---

---

VOL. III.

OCTOBER, 1909.

No. 2.

---

---

*[This Journal, though published with the approval of the Secretary of State for the Colonies, is not official, and the Secretary of State is in no way responsible for the opinions expressed in it.]*

---

---

**EDITORIAL NOTES.**

THE passage of the South Africa Bill through both Houses of Parliament marks the completion of a political achievement as notable as any which history has to show. The concluding stages were far from being merely formal. As a result of a number of conferences with the Secretary of State, the delegates agreed to certain alterations in the text of the Bill, which were regarded as not inconsistent with its principles, with the consequence that it was finally presented to Parliament as a measure jointly agreed upon by His Majesty's Government and by the fully accredited representatives of four self-governing Colonies. The fact that the delegation from South Africa was hardly less representative of the parties in opposition than of those in power necessarily lent further weight to their influence and strengthened their title to speak in the name of United South Africa. In these circumstances any amendment of the Bill by the Imperial Parliament became practically out of the question. But the debates on the measure were nevertheless of quite exceptional interest. In the House of Commons, in particular, a forcible attack was made upon the provisions of the Bill which disqualify persons of non-European descent from membership of the Union Parliament, and leave the natives, except those in the Cape, without direct repre-

sensation. An amendment which would have abolished the "colour bar" was rejected on a division by a majority of one hundred, but not a single speaker defended the restriction on its merits. It was explained on behalf of the Government as an essential part of an intricate compromise, without which agreement among the parties to Union would have been impossible. It was supported on the same grounds from the front Opposition bench. But Mr. Balfour and Mr. Lyttelton were not less emphatic than the Prime Minister and Colonel Seely in their disapproval of the extent to which differentiation between black and white is carried by the measure, and their views were endorsed with absolute unanimity by speakers in every quarter of the House. The Prime Minister expressed an earnest hope that this consensus of opinion at home would carry weight in South Africa and lead sooner or later to a voluntary abrogation of the colour bar. If the change is ever made it is certain that it must spring from a development of opinion in South Africa itself, and not from any attempt at dictation from England. But it was right that expression should be given in a dignified form to the view which may be regarded as universal in this country.

---

Apart from the criticism passed upon these particular provisions, the attitude with which the Bill was received was one of enthusiastic approval, and the third reading was voted unanimously. It is understood that the new constitution will be proclaimed on May 31st, 1910, the eight anniversary of the conclusion of the Treaty of Vereeniging, and no more appropriate date could possibly have been selected. That a war so protracted and so hard-fought should have been followed after so short an interval by a reconciliation so complete was more than the most optimistic could have ventured to hope, and is a remarkable tribute to the freedom and elasticity which British institutions render possible. The Union of South Africa will be in every way worthy to rank beside the two other great unions of self-governing Colonies in the British Empire, and its establishment brings the more systematic organization of the whole Empire appreciably nearer. In the whole course of our history there is no event which may more legitimately be regarded with pride and satisfaction. It is understood that the Prince and Princess of Wales will visit South Africa to open the first Union Parliament, and will make an all-round tour. They will be accompanied by Sir Francis Hopwood.

---

All precedents show that any attempt to control the native question by removing it from the ordinary sphere of local government is doomed to failure. Such an attempt was made when

Western Australia was granted responsible government, but the whole of the machinery devised was soon afterwards given up, and no ill effects have resulted from this. South Africa must, and will, shape its own policy.

---

It is interesting to notice, in connection with the Union of South Africa, that a strong movement is proceeding in Australia in favour of unification. A petition presented to the Commonwealth Parliament urges:—

“1. That at the time when the Commonwealth Constitution was adopted, it was confidently hoped by a large majority of the electors of Australia that large reductions would be made in the expense of maintaining the State Governments.

“2. That practically no reductions have been made, and the establishments of the State Governments are still maintained on an altogether unnecessary scale.

“3. That the experience of six years of Federation has made it clear that no satisfactory legislation in the direction of reducing the expense of the State Governments, or of increasing their efficiency and usefulness, can be hoped for from the Legislatures of the States.

“4. That the continued existence of the State Governments with their existing powers prevents the development of any true Federal spirit in Australia, and tends to perpetuate the State jealousy and provincialism which it is the purpose of Federation to destroy.

“5. That the continued existence of the State Governments, as at present constituted, hampers the efficiency of the Commonwealth Government, and prevents it from exercising its power in the fullest measure for the benefit of Australia.

“6. That the only satisfactory remedy for the conditions described is to be found in the Unification of Australia; the State Governments being retained in existence only for the purpose of dealing, under Commonwealth control, with matters of purely local interest.”

---

The difficulty of the Imperial defence question is that public interest and sympathy cannot well be kept active except by measures of decentralization, and decentralization from a military point of view means waste and weakness. The history of the negotiations over the period since 1887 shows the continual conflict of the two considerations. It may be the best strategy to concentrate your forces, and the best place for defending a colony from attack may be some thousands of miles from it; but such dispositions are not reassuring to the places which are apparently left exposed, and do not help in the least to create that enthusiasm

and public spirit, without which it cannot be expected that money and support will be forthcoming. The payment to which the Australian representatives agreed at the Conference of 1887 was made on an understanding which was not very definite, and which was afterwards put in varying shades of colour to suit different feelings. But on the whole Australian opinion clearly demanded that the vessels for which they paid should be regarded as intended for their coast defence. The general aim should be both to provide for strategic action and to satisfy the requirements of local feeling. Due weight has to be given to the fact that trained men are indispensable as well as ships, and that any scheme which provides such training locally is very valuable even if it involves the detachment of vessels. Nothing but good can come of close discussion of the subject, and the visit of the representatives of the Dominion to this country to confer with the Government has been marked by a distinct practical advance.

---

The visit of the Colonial press representatives to England had much to do with the reduction of press rates to and from Australia to 9d., effected simultaneously on the Eastern and Pacific routes from 1st August. The reduction affects the former much more than the latter route, as the Australian Press Association have practically confined their favours to the Eastern companies. A reduction of the rate on ordinary messages would be a much more vital matter. The Pacific cable is at present, not reckoning the payments for sinking fund and renewal reserve, earning about  $2\frac{3}{4}$  per cent. interest per annum; but including those disbursements the deficit is about £60,000, and any general reduction is sure to increase it. Only about 21 per cent. of the Australian cable business passes over the "all-red" route, and if a reduction is to be justified some better support may reasonably be asked for. It was mainly the Australian mercantile community that agitated for and ultimately got the Pacific cable, but as soon as this scheme had the effect of bringing down the price they as a body ceased to concern themselves with it.

---

The Report for 1908 of the General Manager of the Central South African Railways contains an interesting account of the working of the "white labour experiment." At the present time upwards of 2,000 white men are employed on the railways on unskilled manual labour, and the General Manager finds that "the experiment has been, in the main, quite as successful as any optimist acquainted with the circumstances could have expected." It is true that the performance of the work by white men has led to an increase in cost, even where it has rendered possible a reduction in the number of hands employed; and it is

also true that the white men so employed "find it difficult to make ends meet on their present pay and privileges." But against these drawbacks the General Manager sets three great advantages which have resulted from the success of the experiment.

"1. It has found subsistence and employment for a large number of white men whom it would otherwise have been difficult and costly to provide for.

2. It has established another bond of common interest and mutual trust between the members of the two white races over a wide area in the Transvaal and Orange River Colonies. . . .

3. It has already served to break down in a remarkable degree what seemed to be an insuperable barrier of prejudice on the part of white men to perform for wages manual labour which they regarded as degrading and only fit for natives to perform. It is true that this barrier is as yet only partly broken, but the gaps are now so wide and numerous, in so far as we are concerned, as to be beyond repair. The men have found that labourers' work well done has brought them, instead of degradation, the respect and goodwill of their fellows, and opportunities of improving their positions. Not only are the means of earning a livelihood enlarged to men of their class, but the prospect of employment for white men on a large scale in South Africa is correspondingly increased."

The disinclination of the white man to undertake unskilled labour constitutes, perhaps, the most difficult problem which South Africa has to face in the future, and if the experiment on the Central South African Railways should result in the gradual removal of that disinclination, it will have been of incalculable service to the country.

---

The Royal Commission appointed to consider the trade relations of Canada and the West Indies has arranged to begin its work in Canada, and the British members sailed for the Dominion on September 11th. The Commission will subsequently, probably after Christmas, visit the West Indies. The enquiry is a long and complicated task, and by no means easy to arrange. Any question of differential treatment raises delicate points, but the Commissioners may be able to make a selection of articles which could be admitted from Canada into the islands at a reduced rate, and which are not to any substantial extent exported from this country. That it is highly desirable to improve steamship and telegraph communication between the two places everyone is agreed, and it is probable that these matters will figure in the recommendations.

There is a natural inclination on the part of local producers in any place to agitate for the exclusion of competing imports if it can be contended that any danger attends them. Not a little objection has been urged in South Africa to the importation of oversea fruit and vegetables on the ground that pests are introduced in this way. The objection is rather weakened by the fact that the country has already an extensive supply of these pests in its own productions, and the danger in further introductions from fruit is trifling compared with what it is from trees and plants. The recent report of the Cape Department of Agriculture points out that insistence upon absolute freedom from anything in the nature of a pest would necessitate the exclusion of almost all consignments of fruit that arrive. A reasonable margin must be allowed, and there is not much practical difficulty in fixing it.

---

In British East Africa the year 1908-9 was one of the most bounteous within the experience of settlers in the highlands. There were good harvests of all crops. The spread of cattle disease, however, caused much trouble, and considerable effort will be necessary to deal with the mischief. A hostel has been built on the Kabete farm to accommodate young settlers from home, who will be able here to acquire experience before taking up farming on their own. The Colony has a great advantage in the fact that two harvests of wheat can be obtained in the year, and farmers were receiving from 5s. 8d. to 6s. per bushel at the mill. The cotton harvest in the coast belt has been a very meagre one: cotton requires a long time from sowing to harvesting, and apparently the rains are not sufficiently extended for it. The labour difficulty still awaits solution, and the most favoured idea appears to be a system of indentured Indian labour, with engagements for three to five years, and at a cost of 15 rupees per month, passages included. With four millions of natives in the country it seems curious that the labour difficulty should be acute, but the employer does not find this teeming population where he wants hands. The settlement of small areas contiguous to native reserves has been encouraged, but the plan is neither so safe nor so agreeable to the settlers, who naturally prefer to be side by side.

---

The great trouble in East Africa is, of course, the insects—termites, ticks, and tsetse-flies. Ticks are blood-suckers and transmit blood diseases: their vitality and reproductiveness are remarkable, and account for their myriads. The tick-borne diseases known at present are East Coast fever, red water, biliary fever of the horse, and heart-water of sheep and goats.

More complete records of the distribution of these pests and tsetse-flies are required, and will be eventually accomplished.

---

“ At the present stage of the country's career,” it is observed in the report of the Department of Agriculture for 1908--9, “ State aid and initiative are urgent. Scientific and technical assistance should be given in the conduct of investigations in agricultural problems: such as the control of diseases and insect pests, the collection of trustworthy data, and the fostering of the various branches of industry during infancy. . . . Stock of all descriptions appear to thrive well, most crops belonging to the temperate, the sub-tropical and the tropical zones, can be grown within one part or other of its boundaries, and climatic conditions are, generally speaking, favourable for white occupation.” Much useful work in this direction is being done by the Department, and if the land laws are aggressively criticised in some quarters it should be remembered that the main objects are the creation of a large class of small proprietors and the participation of the State in future years in the increased value of the land.

---

The development of German East Africa in recent years has been remarkable, and the position of their steamship service on the coast commands respect, even if it leads to complaints that the British flag is not represented as it should be. But in making comparisons it should be remembered that the outlets for German capital in their own colonies are very limited compared with ours. A great amount of money, represented by some forty or fifty companies, to say nothing of private enterprise, has been sent from Germany to the Colony. A length of railway of 212 miles is now open, and in six years there will be 680. The exports have trebled in the last eight years. The number of white settlers, however, is still small—about 480. A rapidly growing “overland” trade is due to the Uganda Railway, which thus renders a valuable service to the German possessions, and benefits itself; in fact, the produce of that part of German East Africa which borders on the Victoria Nyanza accounts for more than 40 per cent. of the whole traffic receipts of the railway. The community of interests and the similarity of conditions make the official extracts which we give in this number well worth study.

---

The earthquake of 1907 in Jamaica was followed by prompt and vigorous efforts to repair losses, and the good results were seen in the best revenue in the following financial year that the Colony has enjoyed for several years. In districts suitable for paying products there has been an undoubted increase of prosperity, and a considerable investment of capital for sugar pro-

duction has taken place. Bananas remain the easiest and most lucrative investment, but there is some drawback in the fact that the commercial position depends largely on this risky crop. The planting of more permanent crops, such as cocoa, is, however, increasing more rapidly than ever.

---

The administrative work which is quietly going on in Ashanti and the Northern Territories of the Gold Coast is a good example of the settlement of troublesome countries. The only intercourse between the tribes of such places used to be by fighting, and an entirely new spirit is created when it is shown to them that they can travel about in security. An agricultural show was arranged at Coomassie, and 88 chiefs with over 1,000 followers from the Northern Territories accomplished the long journey of several weeks; but the fear of the Ashanti, which has been such a dominant feature in the life of the people of the Protectorate for so many years, made it extremely difficult to persuade the chiefs to make the journey down, and the boisterous welcome given them on their return showed with what fear their people looked on the visit.

It is reported with satisfaction that it becomes rarer every year now to see men and women without some clothes on, and no doubt this sartorial advance is very significant.

---

In the Annual Report on St. Helena for 1908 Colonel Gallwey takes occasion to correct the somewhat misleading accounts which have been published of the attractions of the Island as a holiday resort.

"With the very best of intentions," he writes, "certain of St. Helena's well-wishers in England have allowed their enthusiasm in the Colony's cause to overrun their better judgment by prompting them to claim for the Island advantages as a holiday resort which it certainly does not possess. The most alluring inducements are being held out by these people through the columns of the English newspapers as to St. Helena's advantages as a holiday resort. Among the advantages claimed are a splendid climate, cheap hotels and boarding-houses, comfortable houses at a low rent, &c., &c. They even go so far as to state that St. Helena possesses 'some of the finest golf links in the world!' The kind thought which prompts St. Helena's well-wishers in England to promote the Colony's interests is fully appreciated, but it is generally recognised that more harm than good must result from misrepresentation, for such misrepresentation can only lead to disappointment among any persons who might decide to visit the Colony on the strength of the inducements held out to them in the newspapers. It would serve the Island's interests better if

only facts were stated. What are those facts? The climate is very healthy, and, although in the tropics, that of the highlands is very temperate and never too hot. There is not a single hotel in the Island, and the so-called boarding-houses in Jamestown might at a pinch accommodate half-a-dozen people. There are no boarding-houses in the country where visitors would require accommodation. There are about six untenanted houses which could be leased at reasonable rents, half of which are either unfurnished or only partly furnished. 'Some of the finest golf links in the world' must be taken as referring to the one golf course of nine holes, there being no suitable site for a second course in the Island. I should be very pleased to see St. Helena become a health and holiday resort. If visitors were forthcoming boarding-houses would soon spring up. It is not to be expected, however, that such establishments will be started on chance. As things stand at present, accommodation for more than a very few visitors does not exist, and any persons proposing to visit the Colony would be wise to ensure beforehand that the accommodation they require is both suitable and available. Visitors, too, must be prepared to find the Island somewhat dull. There are few diversions by day and practically none by night. In any case, the hilly nature of the country and uncertain weather conditions do not conduce to the comfort of night travelling in St. Helena. Taking it all round, the Island's advantages, as far as holiday and health seekers are concerned, lie almost entirely in its healthy climate."

From the same Report, it is satisfactory to learn that the economic situation in 1908 showed a marked improvement, and that so far as the country districts were concerned the year was a good one. In Jamestown conditions were less satisfactory, but much was hoped from the efforts of Mr. A. Mosely, C.M.G., to establish new industries in the Island.

---

The Earl of Crewe has appointed a committee, under the chairmanship of the Earl of Cromer, to organise entomological research in the British Colonies and Protectorates of tropical Africa. An Imperial contribution of £1,000 a year for five years has been granted, and £1,000 a year for the same period will be contributed by the West African Colonies. Mr. G. K. Marshall is Scientific Secretary to the Committee. The importance of the part played by insects in the transmission of disease among both human beings and animals has been immensely emphasized by recent medical research, and the establishment of this new organization is a welcome extension of the already considerable activity of the Colonial Office in the field of tropical medicine.

## THE CANADIAN CIVIL SERVICE.

THE Canadian Parliamentary Session of 1908 was distinguished by the stormy proceedings which took place in connection with the charges of the misdeeds of public officers. The Civil Service Commission appointed in 1907 issued an elaborate report, in which many severe reflections were made on the modes of making appointments. It was alleged that in the working of the Civil Service there was "a constant attempt to evade the examinations"; patronage seemed "to run more or less through every Department"; promotions were few and transference from one district to another in the outer Service was rare; ambition to rise was being largely checked and individual work was deteriorating; the higher posts were being filled by political patronage. Uniform classification was said to have failed and to be practically disregarded; salaries upon the whole were too low and increases based upon individual merit were recommended; promotions were seldom made from considerations of merit, and it was urged that the whole system of political favouritism and patronage should be abolished. Many officials and appointees of this kind were said to be not amenable to discipline. Regret was expressed at the repeal of the Superannuation Act which, it was declared, should be re-enacted with provisions for the support of the widows and orphans of deceased civil servants. An Act on these lines was drafted and appended to the Report.

The question of efficiency was dealt with at length. In the outside Service the Commissioners found that, as a rule, "politics enter into every appointment and politicians on the spot interest themselves not only in the appointments but in the subsequent promotions of officers." It was declared that the officials of this branch of the public service were "without hope and the majority of them in dire need."

But the most sensational part of the report was a statement included in it, but made in particular by two members of the

Commission who had enquired specially into the working of the Marine and Fisheries Department. By way of example of a tremendous indictment may be quoted the remark that "zeal for economy and good management, or pride in the work, is not visible. Perfunctory and mechanical discharge of duties is the rule, with apparently no perception of any need for uniformity." There was also a charge of "lack of conscience," and a not obscure suggestion of dishonest practices. The judgment of the Commission was as follows:—

"Your Commissioners have to confess that the general conclusions which they have formed regarding the administration of the Department are most unfavourable. It seems to have few redeeming features; although there are some, one of which is the presence in the Department of some good men, chiefly, but not wholly in the lower ranks. With a better organization and a better method these might form the nucleus of a good staff. The trouble is not of recent origin, but has been long continued, and is the result of evil methods and practices persisted in for many years. Organization, discipline, zeal for the public service, and regard for economy are all conspicuous by their absence. Money is wasted in small things as in great, because no one seems to have any motive to do otherwise. While there is no real punishment for the most outrageous blundering or the most incompetent service, there is at the same time absolutely no means for the discovery of merit and the promotion of talent. It seems to have been the same under all Administrations, and Government departments, like private corporations and private individuals, having once acquired a distinctive character, find it impossible to change it by any impulse from within."

The publication of the report caused wide-spread sensation. The Government at once took the line that the accusations of the Commissioners, while general and indefinite, reflected on the integrity of the officials generally, and that both in fairness to them and for the protection of the public interest it was necessary to sift them. Mr. Justice Cassels was accordingly appointed to investigate the allegations. Various causes delayed this enquiry. But in Parliament the discussions on the general subject went on. In the Commons, on May 26th, the Hon. G. E. Foster moved a resolution declaring that: "The Civil Service system of Canada should be based on merit and character alone, and all the appointments thereto should be made from candidates whose competency has been established through open competitive examinations conducted under a non-partisan Civil Service Commission." His speech dealt at length with the non-partisan Civil Service of Great Britain and its rich results, its history and general character, its many lessons for Canada; reviewed the

United States system, its struggles, corruptions, and reforms; described Canada as making little or no progress in the condition of its Service; approved the chief conclusions and criticisms of the recent Commission; denounced the patronage system and political influence in appointments; proclaimed the necessity and enormous value of a trained, independent, self-respecting Civil Service based on merit, freedom, and individual manliness.—(*Canadian Annual Review*).

The motion was considered objectionable by the Government in appearance, and was defeated by 72 votes to 30; but on June 17th a Government measure was introduced by the Minister of Agriculture with the following explanation:—"Probably the most important reform provided in this Bill is the establishment of an independent Civil Service Commission. The Commission shall control the examinations for entrance into the Service, also give such certificates as may be required with regard to promotions, increases of salary, and the improvement of the status of the employees. The Commission will control the examinations, and make all necessary arrangements for the carrying out of the work—all, of course, subject to the approval of the Governor-General-in-Council. The Commission is to be composed of two members with the status, salary and tenure of a Deputy Minister. The Commission will recommend the necessary staff required for the carrying out of the work. The second important reform is that entrance to the Civil Service shall be open to competitive examination. At present entrance to the Civil Service is open to those who have passed the qualifying examination. That examination, however, does not entitle any one to entrance. It simply gives the opportunity of entering and the choice is left entirely to the judgment of the nominating power. But under this Bill the entrance will be by open competitive examination, and the nominations to the Service will be in order of merit under the control of the Commission." The Bill was passed, with an important amendment, which made the status of the Commission permanent and the Commissioners irremovable by ordinary Government action. Thus, whatever the truth about the alleged corrupt influences, the agitation brought about a change of enormous importance and significance, the creation of a Civil Service on the lines of that of Great Britain. Whether the charge of general political corruption, against Ministers of the Crown as well as departmental officials, was well founded was a question which divided Canada at the last election, but there can be no denying that it was made by a great number of responsible persons and papers. It was, in fact, freely alleged that corruption permeated every department, and a very large part of the time of Parliament and of the energies of the Government was taken up

in dealing with the subject. This state of things is practically inevitable in a country which has large concessions and contracts to dispose of, unless the Civil Service is kept up to a high level of efficiency and trustworthiness.

Mr. Justice Cassels' report has been issued this year in a sessional paper (No. 38). His instructions were in effect to ascertain the guilt or innocence of any official charged with lack of conscience or of directly receiving bribes or other perquisites. It quickly appeared that the country lost considerably from a vicious system for which the officials were not responsible. The departments were compelled to buy from "patronage lists" of selected firms, and these lists were made out to a greater or less extent in consideration of party influences. The Judge, as might be expected, severely condemned this system, as not only wasteful of money but also demoralising to the officials. "The system," he states, "seems to have been handed down from one Administration to another since Confederation. To my mind the adoption and continuance of the system is absolutely wrong. It apparently is based on the old maxim, 'to the victors belong the spoils,' utterly ignoring the fact that the money to be disbursed is money contributed by the people generally, and not the money of the political followers of the party at the time being in power." We doubt whether the practice was based on the above or any other maxim; it was simply a case of taking an advantage for party purposes, and probably few, if any, Canadians would openly defend it on any ground. It was abolished by the Minister of Marine and Fisheries, so far as his department was concerned, before the Judge reported. An extraordinary feature is that it seems to have been open to private Members of Parliament to direct the placing of orders. Thus: "Q.: So it was not your own independent judgment that was exercised from time to time as to where the work should be done or by whom, or by whom materials should be furnished: that was done upon recommendation? A.: By the Member of Parliament having the patronage." And "Q.: Have the Members intervened so as to govern the patronage list? A.: Yes; they could take any name off the list they wished, and they could add names to the list. From time to time we get special instructions that special work is to be given to special people. Q.: From whom do you get those instructions? A.: From the Members. Q.: Do you obey the instructions? A.: Certainly, sir." In one case it was shown that a wholesale firm in Halifax sold goods to a department at 10 per cent. over retail prices, and the firm explained that "we get the orders for the most part from the fact of our being on the patronage list. . . . Any particular order we would ask the Member at times to use his influence to see we got it."

The examination of the personal cases clearly showed that certain officials took money improperly. Thus one made advances to contractors, charging five per cent., the colourable pretext being that they got their money quicker in this way than if they waited for the official settlement: "denuded of verbiage," the report puts it, "the fact is that he has been exacting a toll of five per cent. on the amounts due by the department to contractors and others who had the privilege of dealing with the department." It is hardly necessary to remark that the firms which made this arrangement do not appear to have been exposed to competition, and "it may almost be assumed that those paying this commission did not pay it out of their pocket, but so arranged that the prices paid to them amply recouped them for such outlay, and the toll was paid by the country."

In other cases direct bribery was proved, and the Judge observes that "the conduct of some of these officials who have been guilty deserves nothing but condemnation. . . . They seem to have been ignorant of the injunction in the Mosaic law against receiving gifts, 'for gifts blind the eyes of the wise and change the words of the just.'" If the Mosaic law is ignored, it may be suggested that a good substitute is a local statute making the giving or acceptance of bribes in such cases a penal offence.

Some recommendations are made at the end of the report, but they do not go so far as to make these transactions punishable criminally. The chief remedy, the Judge says, "lies in the awakening of the public conscience. If the public generally could be brought to view with abhorrence graft and abuse of trust on the part of those administering the public moneys and property, the end of such abuses as have occurred in the past would be in sight." It may be questioned whether any quickening of the "public conscience" would cure the mischief. Judging from the interest shown in the controversy the conscience of Canada in such matters is sound, but there, as elsewhere, crime has to be put down by the strong hand, and it is one of the tasks of modern administration to detect crime in whatever specious disguise it may be concealed.

## THE ROYAL COMMISSION ON SHIPPING RINGS.

THE President of the Board of Trade submitted a tough problem to the body which he appointed to report on shipping rings. We are surrounded nowadays by combinations the object of which is to fix prices and shut out all competition which might interfere with the arrangements made. When the public discovers that a price has gone up and that no one is to be found who will supply what is wanted at a lower figure, it very naturally exclaims that there is a monopoly, and there is a general feeling that any monopoly is mischievous and should be put down. This feeling is largely due to the historical associations of the word. Monopoly has usually implied an exclusive concession by the State, and the power which gave could take away, and was generally sooner or later induced to do so. The modern monopoly is not of this creation, and cannot be dealt with in the same way. It arises out of voluntary combination, and has no legal privilege. In the old case the establishment of a monopoly was an interference with the liberty of the subject. In the new case it is the suppression of the monopoly that would be such an interference. Nothing is gained, therefore, by the use of the word as a weapon of attack, and the consideration of the subject must turn upon the advantages and the disadvantages of the system in practice.

The particular characteristic of a shipping ring is the deferred rebate. The object is to induce shippers not to resort to any other service, and to effect this a percentage, usually ten, of their freights during a certain period, usually four or six months, is eventually paid to them provided they have confined their shipments to the ring's steamers during the whole of the time. Thus, though the shipper enters into no contract to ship exclusively by the ring's steamers, he is rewarded if he does so. In practice the inducement to be "loyal" in this sense is very strong. The reason for this is simple. The rings provide the best

and the only regular services, and the occasions are numerous when a regular shipper has no alternative but to send by them. He might on some other occasion when time is of no great consequence get cheaper freight from a tramp steamer, but in that case he forfeits his rebate on his other shipments, and, generally speaking, he finds that it is not worth while to do it. This would not be the case if the disparity between the inside and the outside rates were much greater than it is, and clearly the charges of a ring are limited by the competition which would be at once called into being if they became generally excessive. The tramp steamer is in the majority, is tied to no route or customers, and is ready at any time to take advantage of a favourable opening. It can therefore only be kept out by a service which, on the whole, is calculated to secure the adhesion of shippers.

A case of a unique character is that of the Straits Homeward Conference. There the principal local freight agents, said to represent about 60 per cent. of the trade, agreed with the Conference to use its steamers exclusively, and the Conference agreed, on certain conditions, to distribute five per cent. of the total freight among them. This arrangement is set out in the Report (pars. 49—51), but in a rather misleading way, as it is not supplemented by the fact that in addition to this special five per cent. there is a further and general rebate of ten per cent. allowed to all shippers who support the Conference. The case, therefore, contains the usual elements, with a special agreement with a limited number of firms added.

A salient feature of the matter is that these shipping conferences have rapidly extended to almost every quarter of the seas. They do not exist in the North Atlantic and Coasting trade. But these exceptions are explained by circumstances peculiar to these quarters. In the Atlantic the importance of the passenger trade is so predominant that this business by itself suffices to support a regular and well-organized service. In the coasting trade recourse to rebates is unnecessary because it is easier to secure guaranteed custom in other ways. Some homeward trades are also outside the system; these are cases where a larger amount of tonnage is shipped than goes outward, and the liners therefore cannot and need not insist on having it all. In all other cases the conference system has established itself, and this generality points to a clear and broad reason. What this is is obvious enough: it is the demand for a regular and organized freight service. If there is no such demand, there is not and cannot be a conference; if there is, a conference is inevitably established. The public, in fact, gets from the system something which otherwise it would not get, and naturally it has to pay some price for this. The benefits gained are undoubtedly very

## The Royal Commission on Shipping Rings. 109

substantial. Some of them are involved in the provision of an organized service, and others are matters of custom. "Advantages coming under the first heading are fundamental in their character, affecting the nature or cost of service, and are due to the organization implied in the conference. Among them must be included the provision of regular and fixed sailings, covering as a rule many foreign ports, and taking place throughout the year, the arrangement of such dates so as to avoid clashing, the determination of rates and classification on a stable basis, and the many other features which distinguish a service from the varying, irregular, and disconnected, even if frequent, opportunities for shipment offered where there is no organization." The advantages offered by vessels of high class and speed are very substantial. The insurance premium on cargo is less, and the cargo is delivered in better order and more expeditiously. The liners are specially adapted to the trade for which they are used. The regularity of freight charges is a feature, the importance of which the Report hardly brings out; buyers want regular supplies at, as far as possible, regular charges, and are willing to pay something for this convenience, as pointed out in our last number (p. 57). The advantages under the second head are different. "They exist in the usages which the Lines in Conference observe in their dealings with the shippers. Thus there is a tacit understanding that Conference Lines will charge equal rates to all, give protection to their shippers in cases where trade competitors by going outside have obtained lower rates, and abstain from carrying goods on their own account. These and other understandings, whether avowed or not, have crystallized into usages, to which most of our witnesses attached great importance. They are usages due to the existence of Conferences, and observed by them towards shippers who give them an undivided support." The system has, in short, with all its features been built up organically in accordance with the requirements met with.

The price which is paid for these advantages is, of course, found in the freight charges, and obviously it would be futile to specify a rate which at any time might be higher than that offered by a tramp steamer, unless in some way continuity of custom is secured. Fixity of arrangements on the liners' side implies some amount of fixity on the shippers'. "Lines which maintain a regular service covering small as well as large foreign ports, and sailing at regular and fixed dates, are involved in greater expense than competitors who choose their sailings, and offer only irregular opportunities for shipments. Moreover, owing to the movable nature of ships, such competitors, if driven off by the Conference from any one route, can resort to other tracks

without suffering any loss commensurate with that incurred by unsuccessful competitors in the general industrial world. Finally, the adoption of some of the improvements whereby transport is cheapened, *e.g.*, the building of ships of larger carrying capacity or specially adapted for particular trades, increases the risk and difficulties of regular lines unless they possess some guarantee of a continuity of custom." It follows from this that a "tie" of some sort is necessary. The most common form of tie is that of contract, and in some cases this was resorted to, but the results were not satisfactory, and it was largely owing to the desire to avoid the inconvenience involved that the system of deferred rebates was introduced.

The trouble is that when once the conferences have secured their position they are able to put up the rates, or some of them, higher than they should be. The Royal Commission, while explaining that it is possible that the position may be abused in this way, state that the evidence in support of the contention that excessive or unfair rates have been charged appears to them inconclusive. This point is dismissed briefly (par. 299), and the somewhat indefinite way in which it is treated will seem to the many people who regard it as the most important question a rather weak feature of the report. But in other ways the report is clear that the system has abuses. "We consider that this is a grave defect in the system which has in the past led to diversion of orders from this country to the United States of America, and thereby discounted the benefits obtained from the system. We consider it advisable, therefore, that some means of checking abuse of the system in this direction should be found." The Commissioners note that in the case of the Straits Homeward Conference an agreement was made by the Conference with certain of the more powerful merchant firms granting them a considerable preference in the form of an extra rebate, and they observe that the circumstances of this case are very exceptional, and may, if the course adopted be persisted in, call for legislation. The South African and West African Conferences were, they consider, shown to have acted in an arbitrary manner, and in the case of the former grievances of a substantial character have been experienced.

At this point in the argument the Commission breaks into two parties. It is exceedingly difficult for any body of men to arrive at the same appraisal of advantages and disadvantages in such circumstances, and it is not surprising to find a minority report which sets out that the advantages of the system are overrated and the disadvantages underrated in the majority report. The majority report is decidedly against the statutory abolition of the

## The Royal Commission on Shipping Rings. 111

rebate system. The signatories consider that on the whole it is generally advantageous, and decline to recommend any control over it by legislation. Their main recommendation is that the shippers and merchants in a given trade should form themselves into an Association, so that they might be able to present a united front to the Conference when any controversy arose. They further recommend that in case of failure to reach an agreement the Board of Trade should have power to appoint a person to endeavour to promote a settlement by conciliation, or on the application of both parties (an unlikely event) an arbitrator to decide the point at issue; and that in cases where it appears to the Board of Trade that there are good grounds for believing that important national or Imperial interests are affected, and where it has not been found possible to settle the dispute by conciliation, the Board of Trade shall have power to appoint a person or persons to inquire into the matter and report to them, it being left to the discretion of the Board of Trade whether their report should subsequently be presented to Parliament. They also suggest the publication of rates and classification of goods.

The Minority Report makes light of the advantages which it is claimed are given by the system of shipping rings. None of these advantages, it urges, are given under any contract which can be enforced at law. It may be replied that they are not the less real on this account; it is the actual system, and not any matter of legal rights, that is on trial. As regards the employment of better steamers, sailing on fixed dates, it argues that "this has been merely an incidental or subsidiary result of the change. It was not the object with which the system was introduced. That object was to put down and prevent competition." All this may be admitted. No one supposes that the Conferences have been established for benevolent purposes, but the question is not one of motives but of results. It is contended at some length that there is a waste, owing to the fact that the steamers of the rings, though not at the time required on the line, are not allowed to "move freely from one part of the world to another, or to pass from one track to another, as the circumstances of the day may require." The answer to this is that it is not true, but in any case "waste" is inevitable when there is depression. Some hardships are referred to, and here the minority report is on firmer ground. Thus the exclusion of British tramp steamers from Singapore has no doubt given an impetus to foreign tonnage, and this result of the system is perhaps its most assailable point. There have been notorious cases of shipments from the United States to South Africa at lower rates than from this country, and it requires a highly philosophical temperament to

watch with equanimity the diversion of trade in this way. But when it comes to actual proposals, the minority shrink from recommending that the deferred rebate system should be made illegal. They prefer that "a real attempt should be made to give effect to a system of conciliation and limited supervision by the Board of Trade." The proposal as set out in detail does not differ in principle and not greatly in procedure from that indicated in the majority report. Sir D. M. Barbour, one of the signatories, adds a trenchant "reservation," in which he gives his opinion that "the proposed associations would be of very little value, and that the nominal power of check given to the Board of Trade would be quite ineffective in practice." But this pessimistic criticism is not accompanied by any clear recommendation of any more drastic policy.

The general conclusion from the evidence seems to be, in the first place, that there is nothing intrinsically wrong in the system, unless all forms of combination for the purpose of keeping down competition are to be regarded as immoral. All classes of suppliers are rapidly finding out that it is better for them to agree with one another than to try to cut one another's throats. The combination is effected in various ways; in a primitive form it is a mere nucleus, lightly held together by a general understanding; under pressure of competition it crystallizes into a solid ring. The result is seen in higher prices and the increased cost of living, but few people seriously suggest, at any rate for present purposes, that such combinations or their arrangements should be made illegal. In the case of the shipping rings, certain practical benefits to the public result in the shape of better services, though it is difficult in many cases to say whether an admitted improvement is due to this or to some other cause. On the other hand, there are some abuses, of which the most serious is that occasionally foreign trade benefits by the elimination of the British tramp. The proposal of the Royal Commission (which has been put forward in this Journal) that the shippers should band themselves together to meet the shipowners in the gate, with the Board of Trade playing the part of guardian angel to both sides, is mild in appearance, and there is no doubt something unsatisfactory to the logical mind in these arrangements of a purely permissive character to which no force of law is given. But in practice the bringing together of representative bodies of two sides, under an organised system of conciliation, is found time after time the most effectual way of obtaining concessions and of bringing about a settlement of disputes. Merchants are really more interested in getting steady and uniform rates than in cutting them down. What they have to fear mostly is having their stocks

## The Royal Commission on Shipping Rings. 113

depreciated by importations by cheap tramps. It is therefore by no means so difficult as it may seem to establish rates which can be accepted as satisfactory by both sides. The efforts of the mercantile associations would be directed towards securing equal treatment for all, reasonable notice and justification of changes, and co-operation against foreign trade which is being given an advantage. If a fair measure of harmony can be attained in these matters, very little more will be heard of the rebate system.

The best way of considering the expediency of making the rebate system illegal is perhaps to work out what would then happen. Clearly the shipowners would distinguish between regular and casual customers, and this could hardly be considered unfair on business principles; but it would introduce the practice of preferential treatment, and make the question of rate continually unsettled. There would be no guarantee of regular dates for sailing. The minority Commissioners think that there is "a natural process of adjustment in such matters," and rely upon evidence representing that "the growth of regular sailings is the consequence, not of the Conference system, but of the development of trade." Of course supply adjusts itself more or less to the demand, and if there is freight there will in the ordinary course be shipping for it; but anyone who has had practical experience knows well enough that tramp steamers regard the advertised date of sailing as a mere expectation of a possibility, and that passengers and cargo will be kept waiting if there is a chance of getting more. The disturbance of regular sailings would probably tend to the employment of slower and inferior vessels. The want of fixity of freights would cause a reversion to the old state of things when the big people chartered tonnage themselves and the small people could only get space by paying them their profit: in other words, it would operate against the small merchant, and would tend to throw business into a few powerful hands. At Singapore, where the system has perhaps been more bitterly attacked than anywhere else, the number of small traders has increased greatly since the Conference came into force. Forward contracts, which are freely made under the Conference system, would be impracticable if freight and tonnage were irregular.

The special enquiry into the South African grievances resulted in no definite conclusion. The merchants there as a body are quite aware that the fixed rates and regular sailings are substantial advantages. The commercial position is now improving, and this fact is, as usual, the best cure for grumbling. If the goods trains to the coast can be filled up instead of running half

loaded the steamers are able to, and probably will, concede better terms. This is really what is now beginning to happen. The export of heavy goods, mealies, oats, &c., is assuming large proportions, and the Conference Lines, it is understood, are agreeing to allow exporters to ship by outside steamers to ports of the United Kingdom, provided no Conference steamer is running to such ports and the rate of freight is not less than to the regular ports of call.

It may be added from our point of view that a Colonial Government importing supplies is not in the position of a merchant in this matter, but in that of the general public. Its interest is to get the lowest possible rates, and it is not so much concerned with their regularity. It might therefore conceivably be to the advantage of a Colonial Government to go outside the ring and support a competing service in cases where this would not be to the advantage of the merchant. But this would mean generally that the Colony would have to charter vessels itself or guarantee business sufficient to support a service, and it is rarely the case that the Government requirements would be large enough for this. The point was seriously considered by the South African Colonies a few years ago, but it was seen on examination that the Government freight was so small in comparison with the whole that it was quite insufficient for such an object. Occasionally there seems to be a tempting opportunity for supporting an outside service which is offering lower rates, but this is a rather dangerous game, for it is pretty certain that if the outsider gets strong support it will be taken into the ring. That, of course, is its object. The result is worse than before, for the ring is so much the stronger. This happened when the Messrs. Houston service challenged the South African Conference. A great amount of pressure was put on the Government departments to ship by these steamers, and though these efforts were not successful, considerable support was given to them by the British South Africa Company. The Messrs. Houston line having established its position, was admitted into the ring. The consequence is what the Minority Report calls an "inflation of tonnage," meaning a greater amount than there is real necessity for, and while this is the case there is little chance for any competitor. It seems, therefore, useless for a Government to attempt to fight a ring unless it sees its way to providing enough cargo to support an independent service. In that case it would ship by the Conference steamers only light goods which are urgently wanted, and give up the rebate. It would have to enter the business of freight agent actively to obtain a homeward cargo, and provide itself with landing boats and all the other appliances

## The Royal Commission on Shipping Rings. 115

which the place might require. But, on the whole, the Conference lines have given the Government favourable treatment, so much so that merchants have frequently complained of such departures from the rule of uniform rates. The whole public, however, benefits by these concessions, and it would be obviously quixotic to insist on the companies levelling up their charges. The Majority Report defends the practice on the ground that "contracts made with Governments stand in a category by themselves, inasmuch as the preferences they accord are not given to one merchant at the expense of another, and the advantage of them is ultimately distributed over the whole community."

The Majority Report defends the practice on the ground that "contracts made with Governments stand in a category by themselves, inasmuch as the preferences they accord are not given to one merchant at the expense of another, and the advantage of them is ultimately distributed over the whole community."

## GERMAN EAST AFRICA IN 1908.

THE Foreign Office Report on German East Africa for the year 1907--8 contains, as might be expected, a good deal of matter which is of interest to the neighbouring British territories of the East Africa Protectorate and Uganda. The trade of German East Africa is divided in this report into the "seaport" trade, by way of the coast ports, and the "overland" trade, by way of the inland frontier and the ports on Lake Victoria Nyanza. Of the latter an interesting account is given in the report:—

"The western or interior sphere of activity is brought into touch with the world's markets by two great channels of communication; in the south by the River Shire and railway *via* Chinde, and in the north by the Uganda Railway *via* Mombasa. The trade *via* Chinde is of comparatively small importance.

"The Uganda Railway, on the other hand, in conjunction with the British steamship service on Lake Victoria, is solely responsible for the unexpectedly rapid growth of the 'overland' foreign trade, notably of the three lake ports Muanza, Bukoba and Schirati, and the surrounding lake districts. In particular, the Uganda Railway has provided an outlet for natural products, the export of which, owing to the heavy cost of portorage, had previously proved unremunerative. The value of such exports, which form the bulk of the 'overland' exports, rose from £37,916 in the calendar year 1904 to £185,288 in 1907, representing an increase of nearly 400 per cent. in three years. Their value in 1907 is equivalent to over 42 per cent. of the total value of the exports from Mombasa during that year originating from the Congo State, Uganda, British East Africa and German East Africa combined.

"This fact would appear to be of no small importance to the neighbouring Protectorate of British East Africa, for it is not

unreasonable to suppose that at least a portion of this 'overland' trade will cease to follow the same route if the projected German railway from Dar-es-Salaam to Lake Tanganyika *viâ* Tabora is connected from the latter place, as has been suggested, with Muanza on Lake Victoria. This project, however, even if it receives the sanction of the Imperial Reichstag, cannot become an accomplished fact in much under eight years' time.

"Meanwhile the German Government appear to be quite content that the Uganda Railway should render a valuable service to German East Africa at a considerable profit to itself, and the suggested extension of the Usambara Railway *viâ* Moschi to Lake Victoria has for the present, at any rate, been dropped, in the not unreasonable belief that the existence of a competitive line would render both lines unprofitable.

"That the Uganda Railway does reap a considerable harvest from German East Africa can be proved by a comparison of the declared values of a given commodity of export at the coast ports and at the interior. For example, in the year 1907 some 117 tons of groundnuts were exported to Germany *viâ* the Uganda Railway of a declared local value of £734, *i.e.*, about £6 5s. per ton. From the coast 107 tons of groundnuts were exported to Germany of a declared local value of £1,473, *i.e.*, roughly £13 15s. per ton. The difference, namely, £739, or £7 10s. per ton, represents the cost of freight, which chiefly went into the coffers of the Uganda Railway. It may be mentioned here that 1,165 tons of groundnuts, of a declared local value of £10,394, were exported to British East Africa in addition to the above in transit to other countries.

"The chief items in these 'overland' exports in 1907 were:—

	£
Ox-hides ... ..	48,068
Goat-skins ... ..	41,708
Wax ... ..	40,937
Rubber ... ..	21,445
Groundnuts ... ..	15,847
Coffee ... ..	4,794
Ghee ... ..	4,634

"Of less importance were sheep-skins, gold, fibre, ivory, cotton, simsim and horns.

"The value of the goods imported into German East Africa *viâ* Mombasa in 1907 was only £37,881, or about one-fifth of that of the exports. This is equivalent to a little over 19 per cent. of the total goods imported into Mombasa during that year."

A good deal of attention is devoted to the handicap to British trade resulting from the absence of any direct British service to East African ports, a subject which has figured pretty regularly in Parliamentary discussions of late years, since the Committee

on Shipping Subsidies, over which Mr. Evelyn Cecil presided, reported that there were special reasons for favourably considering proposals for a subsidized service to East African ports.

*“Direct trade with United Kingdom.*—It is satisfactory to note a slight improvement in the position of the United Kingdom in the direct foreign trade with German East Africa. It cannot be expected, however, that this position will become at all representative so long as the direct carrying trade between European and German East African ports remains a monopoly in the hands of a subsidised German line of steamers. The Deutsche Ost-Afrika Linie maintains a three-weekly passenger and cargo service round Africa in both directions, and in addition a six-weekly cargo service between Europe and East Africa by the Suez Canal. Only the main line steamers call at Southampton, and for passenger traffic alone. It is true that the outward steamers by the west coast route take in cargo there for the Cape, but all cargo consigned to and from London by the east coast route has to undergo transshipment at Hamburg, involving considerable damage and delay. Moreover, these vessels are often heavily laden at the beginning of their journey, and if any freight has to be refused it is naturally the British and not the German shipper who is the first to suffer.

*“Preferential freights.*—But this disadvantage is of small account as compared with that imposed upon British merchants by the rebate which is granted by the Deutsche Ost-Afrika Linie to German firms importing German goods. The company is naturally reticent as to the amount of this rebate, but it is generally stated in British Indian commercial circles to be not less than 10 per cent., and in some cases to amount to as much as 20 or 25 per cent.

*“Absence of a direct British line.*—It is certainly possible to ship goods from London to German East African ports in a British bottom, namely, by the four-weekly service of the British India Steam Navigation Company to Zanzibar, and thence by native dhow. This course, however, involves transshipment at Aden and again at Zanzibar, and the damage and delay entailed thereby, and even more by transport in open dhow during the heavy tropical rains, make this route impracticable for goods of a nature in any degree fragile.

“It might be urged that the existing German line carries British goods to East Africa more cheaply than a British line could afford to do so. This contention, however, does not appear to be supported by facts. Reference has already been made to the rebate on freights and the preferential treatment in general which is enjoyed by German shippers by the German line. This is in itself a severe handicap to British trade on the coast, suffering, as

it already does, under the disadvantage of dependence upon a foreign line, which is naturally none too eager to encourage it.

“*High freights.*—But there is another point for consideration. The Deutsche Ost-Afrika Linie being in the enjoyment of a practical monopoly, does not fail to charge monopoly prices; freights have increased accordingly, and are now maintained at a very high level. In the year 1907, when a direct British line of steamers was running between Zanzibar-Mombasa and London, the freight charges of the Deutsche Ost-Afrika Linie between those ports averaged £1 16s. per ton. The British East Africa Line, on the other hand, carried goods between East Africa and London at a rate which sank from £1 15s. to 7s. per ton. It is only fair to add, however, that the latter excessively low rate was the result of an unfortunate and exceedingly ill-timed freight war with the British Indian Steam Navigation Company, which speedily resulted in the service of the former company being discontinued. Little emphasis can therefore be laid on this point as an argument, but the fact that the Deutsche Ost-Afrika Linie, having recovered its monopoly, straightway raised its freights to £2 5s. per ton in 1908—the rate of freight homewards from East Africa to London now averaging as much as £2 15s. to £3 per ton—would appear to provide a not unreasonable proof that British goods are carried to and from East Africa at the present time at a cost considerably above the margin of reasonable profit.

“*Passenger fares.*—The single 1st class passenger fare between Southampton and East African ports (Mombasa, Tanga, Zanzibar and Dar-es-Salaam) by the east coast route was until recently £42 10s. This was increased by 10 per cent. at the end of 1907, the increase taking effect to all ports by the east coast (Suez Canal) route. Return tickets cost double the single fare, less 10 per cent.

“*Bombay Line.*—In 1907, when a British line was running between East Africa and Bombay a deck passage to the latter port cost about £2 5s. In 1908, after the collapse of the British line, this fare was raised by the German line to £3.”

A fuller account of the situation is given in a later section of the report, and the information which it gives as to the relation between the Deutsche Ost-Afrika Linie and the German Government is sufficiently interesting to deserve quotation in full:—

“*Shipping and navigation. Monopoly of Deutsche Ost-Afrika Linie.*—Communication between German East Africa and Europe is maintained by the Deutsche Ost-Afrika Linie (German East Africa Line), which in fact holds an absolute monopoly of the direct passenger and cargo traffic between those countries, and occupies a very predominant position on the East African coast in general.

“ This line, which sent its first steamer to the east coast of Africa in 1889, now possesses a fine fleet of 20 steamers, ranging from 6,300 to 2,100 tons, which maintain a three-weekly passenger and cargo service from Hamburg round Africa by both east and west coasts, a six-weekly cargo and mail service between Hamburg and Durban, and a regular service between Bombay and Durban *viâ* East Africa, branching from the main line at Mombasa. The service from East Africa to Bombay is three-weekly, but in the other direction at intervals of 10 days, every third steamer returning to Bombay direct from Durban.

“ *Main line.*—In addition to the larger of these vessels, two of the finest steamers of the Woermann Line (6,500 and 6,300 tons respectively), and one of the Hamburg-America Line (6,400 tons) now take part in the main line service. This arrangement is the outcome of an agreement concluded in the latter part of 1907 between the interested companies and the Imperial Government whereby the Deutsche Ost-Afrika Linie took over the mail and passenger service of German South West Africa from the other two lines, which in return for this relief transferred the three vessels in question to the Deutsche Ost-Afrika Linie service.

“ The points of call by the east coast route are:—Hamburg, Rotterdam or Flushing, Southampton, Lisbon, Tangier, Marseilles, Naples, Port Said, Suez, Aden, Mombasa, Tanga, Zanzibar, Dar-es-Salaam, Mozambique, Chinde, Beira, Delagoa Bay, Durban, East London, Port Elizabeth, Cape Town, Lüderitzbucht, Swakopmund, Las Palmas, Southampton, Antwerp, Bremerhaven, Hamburg, and conversely by the west coast route.

“ The contract speed of these vessels is 12 knots an hour between Naples, where the mails are transferred, and Dar-es-Salaam; for the rest of the voyage it is only 10½ knots. The company has undertaken, however, to increase these speeds if required to cope with any foreign competing lines.

“ *State subsidy.*—The Deutsche Ost-Afrika Linie in return receives from the German Government a considerable subsidy, which was raised in 1900 to its present amount of £67,500. The chief object of the Government in increasing this subsidy appears to have been the promotion of German trade on the African continent; the result achieved in this respect, as far as German East Africa is concerned, is referred to in other parts of this report. There undoubtedly existed other motives, however, in the desire to encourage German ship-building, to secure German agencies for German commerce, to ensure the independent carriage of mails, and to avoid the inevitable damage and delay involved by transhipment.

“ *Need of a British line.*—It would, of course, be impossible for a British line without State aid to compete with a line as

firmly established as the Deutsche Ost-Afrika Linie and backed by a heavy subsidy, but there would appear to be equally little doubt that a subsidised British line of steamers, apart from all other considerations, would prove an immense boon to British interests and promote the sale of British goods in German East Africa as in the rest of East Africa generally. Moreover, the passenger traffic between Europe and East Africa, which is especially heavy—not infrequently congested—during the first and last quarters of the year, is by no means a negligible quantity, for a large majority of the passengers carried are British, and it is not unreasonable to suppose that these would prefer to travel under the British flag, especially if the accommodation compared at all favourably with that offered by the existing German line.

*“Communication with the United Kingdom; cargo traffic.—*Reference has already been made to the fact that all cargo passing between London and East Africa is exposed to the damage and delay of transshipment at Hamburg. The main line steamers call at Southampton\* in both directions, but are only allowed by the terms of the contract to stay long enough to deal with passenger traffic. The intermediate line, which carries only cargo and mails, does not touch the United Kingdom at all. Hence all cargo from London must be sent first to Hamburg and there transhipped.

*“Bombay Line.—*The Bombay Line is now served by nine vessels of 3,400 to 2,100 tons, the agreement with the Woermann and Hamburg-America Lines having enabled the company to transfer to this line three of their smaller vessels which until recently took part in the main line service, thereby securing a greatly improved service with India. These steamers—which carry passengers, mails and cargo—call at all the ports between Durban and Mombasa served by the main line steamers, and in addition at the smaller ports of German East Africa, and at Inhambane and Lamu. They also visit Madagascar (Majunga and Nossi-Bé), Seychelles, Goa and Porebunder at less frequent intervals or when sufficient inducement offers.

*“Financial position of Deutsche Ost-Afrika Linie. —*The company reports for the year 1907 a surplus of £82,211, showing a decrease of £1,114 compared with the year 1906. No dividend was paid to the shareholders, all but a minute fraction of the surplus being written off. This unsatisfactory result is attributed in part to the general commercial depression and to the restrictions imposed upon the company by the terms of the subvention agreement. Particular local influences, however, affected the various sections of the service in different ways.

---

\* The point of call in the United Kingdom was changed from Dover to Southampton in July, 1908.

“The traffic with British South Africa suffered heavily from the sharp competition of the British lines, the passenger traffic being especially small owing to the relatively low speed of the German steamers and the additional delay caused by calling at the two ports in German South West Africa.

“To German East Africa the passenger and cargo traffic—especially the latter—showed a decrease from 1906, owing to the temporary cessation of railway construction, but a great recovery in this respect was to be expected in 1908 and the following years, owing to the unprecedented railway extensions which had now received the sanction of the Imperial Reichstag.

“On the other hand, there was a considerable increase in exports from German East Africa, and still more satisfactory results are anticipated from the increased cultivation of sisal, rubber and cotton. Exports from the German territory round Lake Victoria *viâ* Mombasa also largely increased.

“In spite of the alleged unsatisfactory financial position of the Deutsche Ost-Afrika Linie as a whole, it is impossible to believe that the service is anything but remunerative as far as the East African section is concerned. It is a rare occurrence for a vessel of this line to arrive at or to leave East African ports without a heavy cargo and a full complement of passengers. The great majority of the passengers from Europe by the east coast route disembark at East African ports, notably at Mombasa and to a less extent at Dar-es-Salaam. On the homeward voyage by the same route the vessels generally carry a large number of British passengers from Durban and Lorenço Marques, and it is evident that this longer but more interesting route to the United Kingdom is increasing in popularity with travellers from South Africa, with whom time is no object as compared with the pleasure of visiting fresh and little-known places.

“It can only be assumed, and there appear to be ample grounds for assuming, that the sections of the line which, so far from proving remunerative, consume the profits of the east coast sections, are that between Europe and the Cape by the west coast route, where the line has to compete with the speedier and better known British lines and the section between Zanzibar and the Cape.

“*Bombay Line.*—The financial position of the Bombay Line, which has now been improved by the inclusion of three vessels from the main line, is pronounced to be unsatisfactory.

“Reference has already been made under ‘Trade with the United Kingdom’ to the disabilities under which British trade suffers in respect of high freight charges and the rebate granted to German shippers.”

The report contains some interesting remarks upon the subject of Indian and European immigration into German East Africa.

*“Indian immigration.*—The immigration of British Indians into German East Africa appears to be somewhat increasing, the number for 1907 being computed at about 200. This increase is no doubt due in part to the prohibitive measures adopted in British South Africa against Indian immigration. Their presence is regarded with favour by the Colonial Government, who consider that they exercise a very useful intermediary function as small shop-keepers and retailers to the natives. They set up their small shops wherever an opening is to be found, and there are no towns and few villages of any importance in the interior where one or more of them are not to be found.

“There are others, however, and they appear to form the large majority of the white population, who regard the immigration of Indians with extreme disfavour, depicting them as only waiting for the extension of the railways to swarm over the whole country and get possession of the best part of the trade of the interior.

“It is difficult to understand why the presence of the Indian should actually be so undesirable for East Africa. He is accustomed to a tropical climate; he is a born merchant and man of business; and it is scarcely his fault that the idleness and lack of enterprise of the native African has given him a practical monopoly in the small retail trade with the coloured population. Moreover, the Indian does not need the reserve of capital which is an absolute necessity to the small European shopkeeper; he can exist on an amount of food and capital which would be an impossible pittance for a European, and under conditions in which a European in a tropical country would quickly go to the wall. Again, as a skilled mechanic and artisan he far surpasses the native, and he can accept a rate of pay which, from its lowness, precludes any possibility of competition by a European. His unpopularity may be due to a large extent to his reputed extortionate dealings with the careless and improvident native as moneylender and pawnbroker.

*“European immigration.*—An increase considerably above the average is reported in the numbers of European immigrants to German East Africa in 1907, and a still larger increase is expected to result from the strong Colonial movement which has recently shown itself in Germany. A better class of educated immigrants is observed with much satisfaction by the Colonial Government, but it is confessed that there are still many whose ignorance and the carelessness with which they face their new life, and their consequent dependence upon the Government for

assistance in the slightest circumstances of difficulty, render them a hindrance rather than a help to the development of the Colony.

“The type of colonist really needed is the man of some practical experience of agriculture, with a more than vague idea of the difficulties which will beset his path, and possessing above all a reserve of capital large enough to tide him over the times of failure which possibly may, and in many cases probably will, meet his first efforts as a planter. The small settler cannot hope to succeed without very great efforts on his own part, and, beset as he is with the many difficulties arising from limited resources, he is inclined to regard such restrictions or regulations as the Government may see fit to impose upon his operations—in regard especially to such matters as the recruitment and payment of labour—as an unwarranted interference with his own personal liberty and an uncalled-for assumption of regard for the welfare of the native to his disadvantage.”

It is instructive to find that the labour questions, which have caused so much anxiety to the British East Africa authorities, have their close analogies in the German possessions.

“*Labour question.*—Much is heard on all sides among the planters of German East Africa about the so-called ‘labour question,’ and the subject is frequently discussed at length, and often with considerable heat, in the columns of the Colonial newspapers which are published at Dar-es-Salaam and Tanga.

“The impartial observer finds some difficulty in believing that an actual scarcity of labour can possibly exist in a country possessing a native population of some eight or ten millions as against only a mere handful (479) of planters. But although the material is certainly present in abundance, there undoubtedly exists a very great difficulty in the matter of bringing it to the agricultural districts and supplying it to the planters. In considering this difficulty it must be borne in mind that European undertakings are at present concentrated in a comparatively small area at a few centres, such as Usambara, Moschi, and on the Pangani River, and that natives will not be induced to leave their far distant homes in the interior to work on these plantations, unless they are convinced that they will benefit their condition by so doing. It is obviously absurd to contrast the vast population of the country with the comparatively minute needs of the European planters, and to deduce therefrom the fact that the native is incorrigibly lazy and should therefore be compelled by constraint or force to work on the plantations. The East African native is undoubtedly lethargic and unambitious for himself, and the development of the country and the needs of the European planters are matters of supreme indifference to him. His own needs are few, and lie chiefly in the region of his stomach,

and he is sufficiently human not to want to work longer than the satisfaction of these needs demands. In these circumstances it is not a compliment to his intelligence to expect him to undertake laborious work under a European task-master, who is practically, if not technically, free to impose arbitrary conditions of labour and to withhold part of his pay in the shape of fines imposed at his own discretion, without any practical means of redress on the part of the native.

“The first step, therefore, in the solution of the so-called ‘labour question’ must be the more considerate treatment of native labourers by planters, who, faced as they are by all kinds of difficulties, may perhaps be excused, though not justified, in regarding the native as existing merely for the satisfaction of his own needs and, when the native does not see eye to eye with him on the subject, in feeling resentment against a Government which refuses to come to his aid by passing a law for the compulsion of labour.

“The Government, on the other hand, has espoused the cause of the native, and while prepared to render every possible assistance to the planter in facilitating the recruiting, transport and supply of labour, is determined not to countenance compulsion in any shape or form. A Labour Ordinance framed in this sense is shortly to be adopted, and it is hoped that it will do much, by the impartiality of its terms, to solve the labour difficulty.

“A final solution of the question, however, is considered by many authorities to exist only in the extension of the railways. It is obvious that these extensions will render possible the transport of labour from great distances to the locality where it may be required at the moment, with a great saving of time and expense. Further, it is said that the extension of the central railway to Tabora *via* Kilimatinde will open up a country which is eminently suitable for European plantations, and will thus lead to the decentralisation of such undertakings. Above all, this railway when completed will tap the Wanyamwesi country around Tabora, a populous district noted for the excellence of its labour.

“Other critics find the only solution of the labour difficulty in the taxation of the native up to a point at which he will be compelled to leave his small plot of ground and become a wage-earner.”

The German Government is showing considerable activity in the matter of railway construction, and full information is given as to the new railways either definitely sanctioned or projected.

“*Railway extensions.*—The year 1908 will remain a red-letter year in the history of the Colony by reason of the sanction

given and the sum voted by the Imperial Reichstag for very considerable railway extensions.

*“Usambara Railway.*—The extension of the Usambara Railway has been sanctioned to the right bank of the Pangani River at the foot of the Pare Range, a distance of 28 miles beyond Mombo, the present terminus. The estimated cost of this extension is £175,000, or over £6,000 per mile. It is expected to be completed towards the end of 1910.

“In addition to this, the sum of £7,000 has been voted for preparatory work in connection with the further extension of the line to the foot of the Kilimanjaro and Meru Mountains, and £3,000 to form a reserve fund, making £192,500 in all.

“The contract for the extension has been given to the firm of Lenz and Co., who built the section between Korogwe and Mombo; work was commenced about September, 1908, and some 11 miles of rail had been laid by the end of the year.

“The land on both sides of this extension has already been fully taken up. The further extension of the line to the Kilimanjaro is regarded as urgent, as there are already large European plantations in existence at its foot, which at present have no other outlet for their produce than across the British border, as ox-transport is rendered impossible by the presence of the tse-tse fly.

*“Central Railway.*—The extension sanctioned for the Central Railway is a much larger and far more important one, namely, from Morogoro to Tabora *via* Kilossa and Kiliamtinde, a distance of 440 miles. The estimated cost of this extension is £3,500,000, or nearly £8,000 per mile, and a further sum of £750,000 has been granted for the purchase of additional shares in the Deutsche Ost-afrikanische Eisenbahngesellschaft.

“The contract for the extension was given to the firm of Philip Holzmann and Co., who were also the successful contractors for the Baghdad Railway. Work was begun in July, 1908, at various points along the route, and by the end of that year the rail was laid as far as the Mkata River, some 20 miles beyond Morogoro. It is estimated that the whole extension to Tabora will be completed by the end of 1914. The first section between Morogoro and Kilossa (51 miles) is likely to be completed by the end of March and opened to traffic by the end of June, 1909.

“The requisite funds for these extensions, which amount to a total of nearly £4,500,000, will be provided in the form, not of an Imperial grant as hitherto, but of a Colonial loan, which will have to be extinguished and the interest paid by the Colony itself.

*“Advantages anticipated.*—The advantages which are expected to accrue from the extension of the Central Railway to Tabora are, from the agriculturist's point of view alone, the

opening up of the rich Kilossa district to European planters; the facilitated export of cattle from the rich grazing land of Ugogo, Turu, &c., which the existence of cattle sickness has rendered almost impossible up to the present; the facilitated supply to European planters on the coast of labourers from the thickly populated Unyamwesi district; and the increase of the productive power of the country by popularising the culture—to mention only the most important native products—of cotton, groundnuts and rice.

“The continuation of the Usambara Railway to the Kilimanjaro and Meru Mountains is expected to result in the opening up of broad districts to European plantations of rubber, sisal and cotton; the further exploitation of the rich timber possession of West Usambara; and the creation of a receptive market for the agricultural and animal products of the settlers in the healthful district at the foot of those mountains.

“*Projected railways.*—The ultimate destination of the Central Railway will probably be Ujiji on Lake Tanganyika, which could be reached in about four years from Tabora. There does not appear to exist, at present at any rate, any idea of extending the Usambara Railway beyond Mount Kilimanjaro. Should it be found desirable to possess a line between Lake Victoria Nyanza and the coast, the Central Railway could be extended from Tabora to Muanza, an undertaking which would occupy about two years. At present the Uganda Railway performs a very valuable service for German East Africa by carrying the bulk of its ‘interior’ trade, and the Imperial Government appears willing that it should continue to do so, even to the great pecuniary advantage of the British line, rather than enter into a competition, which would not only entail expenditure out of all proportion to the advantages obtained, but also probably result in the financial embarrassment of both undertakings. On the other hand, however, the Government appear to be fully alive to the fact that railways, either projected or actually under construction, are threatening the land frontier from Portuguese, British and Congolese territory with the loss of a considerable ‘interior’ trade.

“*Nyassa Railway.*—The much-talked-of railway from the coast to Lake Nyassa still remains in the clouds, and it is not likely to take definite shape at any rate until the two more important lines are well on their way to completion. The starting point at first suggested for this line was in the neighbourhood of Kilwa, but it appears that the hinterland of Kilwa has a very sparse population—it was decimated in the late rebellion—and it is therefore probable that the line, if it ever becomes an accomplished fact, will take the form of a branch line from the Central

Railway, either at Morogoro or Kilossa, and run thence south-westwards to Wiedhaven *via* Mahenge."

In concluding a report which is replete with information and of more than usual interest, Mr. Douglas Young writes as follows:—

"Although it is difficult to restrain all expression of enthusiasm at the great strides already made in the development of German East Africa, any attempt to predict the future of the country would be peculiarly rash at the present moment. The Colony now seems to have reached a critical stage of its existence. On the one hand, it has passed so far and with such conspicuous success from the purely experimental stage that large interests have now been staked in it; but, on the other hand, it would be unwise to augur a brilliant future from this first flush of prosperity, until sufficient time has elapsed for that success to be maintained.

"The future success of the country seems largely to be bound up with the success of the European plantations, which is in turn dependent upon various internal and external conditions, such as the supply of native labour, the continued possibility of extensive cultivation, the cost of production, and the maintenance of prices at the present level.

"But there is another important point for consideration. The Colonial Government is faced with the necessity of reconciling the somewhat antagonistic elements which compose the economic life of the Colony—a problem not unknown in East Africa. Firstly, there is the native population which owned the land before the German occupation, and expects the pledges given by the protecting Power to be fulfilled. Secondly, there is an alien element in the Indian population, chiefly composed of British-born subjects, who have done much to develop the trade of the country, and demand in return security and recognition in the land of their adoption. Lastly, there are the planters and settlers, who have staked hopes and fortune in the Colony and demand from the Government assistance in their undertakings, even at the expense of the native and Indian populations, whose existence in the country they are inclined to tolerate only in so far as it furthers their own interests. In addition, there are the people at home, who ultimately provide the Colony with the means of existence, and consequently demand a voice in the direction of affairs.

"In one important particular, however, German East Africa would appear to differ from, and hold an advantage over, the neighbouring Protectorate. It occupies an acknowledged premier position among the Colonies of the mother country, who can in consequence lavish upon it her chief attention and support, and

in it are centred the chief hope of that long dormant spirit of colonisation which has found recent expression in the so-called 'Colonial movement' in Germany. As a result of this movement it has been visited within twelve months by both the Chief Secretary and Under Secretary for the Colonies. As the immediate outcome of the former visit, a considerable scheme of railway extension has been sanctioned. In the latter case the visit comprised a long 'trek' from Lake Victoria Nyanza to the coast by way of the Kilimanjaro highlands, and its ultimate effect upon the future development of the Colony is awaited with almost feverish interest by the colonists."

## QUARANTINE IN THE BRITISH WEST INDIES.

In 1904 the second West Indian Quarantine Conference met at Barbados, and all the Colonies there represented, except Jamaica, entered into a convention in 1905. They adopted as quarantine law the Regulations drawn up by the Conference, and we launched on a new era with bright hopes. Now, in 1909, there is throughout these Colonies a feeling of dissatisfaction with the existing quarantine arrangements. The uninstructed lay public now regards with alarm the relaxation of the old precautions as much as it formerly resented the restrictions imposed by the shot-gun quarantine system; the Governments and health officers of the several Colonies are still mutually distrustful, and there is not yet a feeling of unity of purpose and action; and the thoughtful medical bystanders regretfully admit that in the West Indies we are no nearer the ideal hoped for as a result of the Conference and conventions.

As a delegate to the Barbados Conference the writer is loth to believe that this unhappy state of things is altogether to be attributed to fault in our work. Our regulations were first drafted by Theodore Thompson, an expert of the highest authority, himself a representative of Great Britain at the Paris Conference of 1903, on the lines of the regulations adopted by the International Sanitary Convention. They were discussed in minutest detail, amended and added to in a long sitting of eleven days by men who had great experience of West Indian conditions. It may be mentioned that the scope of the West Indian Convention is wider than that of the International, in that it covers small-pox and yellow fever as well as plague and cholera.

Further, there has been established, in accordance with the suggestion of the Conference, a Central Quarantine Authority, on which all the contracting Colonies are represented, to suggest from time to time alterations of the Regulations which advance of knowledge or new conditions may render expedient.

## Quarantine in the British West Indies 131

The British West Indies may, therefore, be considered well equipped and advised in matters of quarantine, and yet we are not satisfied, and things do not work smoothly. It may be useful to examine our position in the hope that we may, in part at least, find explanations of our shortcomings.

While the writer is not actually employed in quarantine work, yet he is in a position to learn much of the official side of it, and has often to act as health officer. Also as a medical man and a West Indian, acquainted with nearly all the contracting Colonies and most of their health officers, he thinks he can appreciate most of the phases of the question. It is not proposed here to present a scientific or logical proof of any theory, in fact such a course could only cause offence and increase resentment between the Colonies if one pursued it; but merely to express the convictions of an observer on a subject in which he is keenly interested.

In the first place let us compare the principles which underlie the old and the new quarantine measures. The conditions of modern life with its free inter-communication, trade and travel render the shot-gun system of quarantine unbearable, and all civilized countries are in consequence getting rid of it. The inconvenience to the people in the infected place, the absurd restrictions of trade, the financial loss to individuals and governments are in no way compensated by the partial protection from diseases which somehow still elude the most stringent precautions.

In the pre-convention days I have known a steamer refused pratique in St. Vincent because, while working cargo at Barbados, where there was small-pox, the rope sling had been handled by Barbadian lightermen and returned on board. I was once unable to get from Barbados a case of calcium carbide, which had been warehoused there for transhipment to St. Vincent, because Barbados was in quarantine, and all cargo thence was refused. Recently, since the convention of the British Colonies, a lady who embarked from St. Vincent and stayed some days in St. Kitts *en route*, was detained fourteen days at a quarantine station in the Danish island of St. Thomas because there was plague at Trinidad, and St. Vincent and St. Kitts were not imposing shot-gun quarantine against Trinidad.

And this condition of rigid suppression of trade had to continue for months; the routes of steamships were sometimes dislocated; private, commercial, ecclesiastical, and official business had to be postponed, or time had to be lost in irksome confinement in small quarantine stations or smaller vessels. All this stringency of the old system was based on the simple principle of excluding every theoretical possibility of infection, however remote.

But the principles embodied in the new regulations are firstly to find the least precaution necessary to exclude probable infection; or at any rate, having regard to all circumstances, to accept a reasonable risk and make a practical compromise between convenience and safety. Secondly, it is intended to direct our precautions against the known modes of infection of each disease so as not to waste effort in useless measures. Thirdly, each place is expected to put itself in such a state of internal protection that chance infection from without will have but little tendency to spread. And lastly, while free pratique is granted to healthy ships, and free entry under surveillance to healthy persons, each infected Colony is required to protect its fellows in the Convention by early notification, by examining persons before embarkation, and by disinfection of ships and their contents before sailing. The essential principles of modern quarantine, therefore, are to avoid exportation rather than to prevent importation of disease, and by the specific measures of internal preventive medicine to reduce the means of spreading disease to a minimum. Such internal measures are vaccination, mosquito and rat destruction, and a safe water supply, as well as efficient arrangements for isolation.

Formerly each place jealously concealed the fact of infection from the others, and without regard to the safety of its neighbours selfishly tried to protect itself from the rigours of quarantine. By reducing these hardships of quarantine almost to *nil* the new Regulations sought to remove the temptation to concealment. There has been, therefore, in every respect a complete subversion of the old ideas of quarantine to which West Indians were accustomed.

But there is one weak point, at any rate for the West Indies, in regulations drawn on such advanced lines, which we may here consider. They imply a mutual trust and mutual protection, and their efficiency must largely depend on the action of the infected place itself. At the Barbados Conference the question of enlarging the sphere of the Convention was discussed. It was suggested that the Imperial Government be asked to approach the foreign Governments with a view to obtaining a general West Indian Convention. Our regulations were made consistent with international and Pan-American quarantine law to facilitate a general agreement. But it was held that such a recommendation was beyond the scope of our mission, and the subject was dropped. Still we hoped that it was the intention of the Colonial Office to do something in this direction, for it was a logical and necessary corollary of our work. However, no such extension of the Convention has yet been made, and we are now in the position of possessing ideal quarantine laws based on the principle of mutual

protection, which we have to apply to cases where no mutual agreement exists. The British Colonies are in convention, but they are sandwiched with foreign Colonies, and have besides much speedy communication with several independent states, none of which are in convention with us.

We should therefore have two sets of quarantine rules to meet these two conditions of intercourse with convention and non-convention places.

Now the existing anomaly, besides being a weakness of position, also causes a want of uniformity. One Colony considers it has no right to treat arrivals from non-convention countries, except as permitted by the regulations. Another thinks the regulations only binding when a convention Colony is being dealt with, and in practice treats outsiders arbitrarily. Another, again, makes a separate law to govern quarantine of non-convention places. This diversity cannot, of course, affect the quarantine practice as between two convention Colonies, but the want of uniformity unsettles the mind of the public, and to some extent leads to distrust between the Colonial Governments. For example, one Government may impose a stringent prohibition against Venezuela for plague, and in a spirit of self-righteousness regard her neighbours with suspicion as possible channels of infection.

It has been pointed out that the Regulations are intended practically to remove the obstructions to trade and reduce the inconvenience to travellers to a minimum. Landing from a "healthy ship," that is, one on board which there has been no case of "infectious disease," a passenger is only required to present himself for surveillance for a few days, and by convention no charge should be made for this. The fact of infection naturally keeps tourists and visitors on pleasure away from an infected place, but that is the only loss that need be suffered through a frank admission of infection. But the public is long in learning this. They cannot realize that the Convention does not bind, but loosens the chain of quarantine. They still think of the old regime, and when infected a community looks with dismay at an agreement which compels it to declare itself so. On the other hand, the lay public is slow to believe that measures may be practically efficient for protection even though they appear, in comparison with the old methods, very lax.

We have, therefore, seen a Colony agitating to relax the stringency of notification for a disease with which it was itself infected, and at other times clamouring to have the law more prohibitive against infection in another place.

Every layman in the West Indies thinks himself competent to have an opinion and express it in print on technical matters of all kinds. And every unofficial is ready to condemn any action of a Government, even though it is of quite a special nature outside of common knowledge and has been advised by experts. It is perhaps hard for people in Britain to understand this phase of West Indian thought and life. The man in the street in London does not trouble himself to criticize technical matters outside the sphere of his own study and experience, even though they are matters of public concern. He, as a rate- and tax-payer, is employing special men to know, to advise, and to do; and he is satisfied that he is getting best work for his money by letting experts do it. To some extent, no doubt, the behaviour of the West Indian is due to the smallness of the communities. Those who are employed as experts in any line are familiarly known, so that they are after all prophets in their own country. The only remedies, perhaps, for the opposition of the public to progress are time and education of public opinion.

The fact that our quarantine procedure is not in agreement with that of the foreign places with which we deal operates seriously against the success of the Convention. This comes about chiefly through the action of the steamship companies. When proceeding to places where our Convention rules do not apply, a steamer is compelled, no doubt, to safeguard herself against the rigid quarantine still imposed by those places, or which it is feared may be imposed. But when ships are regularly trading between Convention Colonies it is surely possible for the captains, agents, and directors to learn the quarantine requirements of the Convention and govern their conduct accordingly. In practice, however much the Colonies may try to free themselves and each other from restrictions, the aims of the Convention are defeated by the steamship companies. They arbitrarily impose restrictions, deposits, and prohibitions based on the old lines or invented by themselves. The tables are now turned, and it almost seems as if the ships were working off an old score for the disabilities to which they were subjected formerly in the name of quarantine. A health officer often cannot tell what a ship may do in respect of his port, what she may require of a passenger, or even whether she will take passengers.

This more than anything confuses the public and keeps up the old ideas of quarantine. We say that quarantine is practically abolished, and yet they find almost as much difficulty in travelling as before.

The most lamentable failure of the Convention is seen in the distrust which still obtains between the Colonies. We have seen

that this was natural before the signing of the Convention, and the old feeling no doubt takes time to fade. But it is to be feared that there is still grave cause for distrust. The Governments, inasmuch as they are all answerable to the Colonial Office, and have besides the ultimate good of the Colonies in view without consideration of immediate and personal interests, act in good faith; but the Colonies do not yet believe in the good faith of each other. The health officers, as far as they carry out their duties conscientiously, are not to be blamed, though, like other mortals, they may sometimes make mistakes. The very nature of their work on the new lines makes them realize the wideness of scope of their responsibilities; that they should not be concerned only with the interests of a single place, but should form together a preventive system extending over the whole Convention area. But they do not know each other enough, or sometimes at all, so that each man while trying to act fairly himself does not feel quite sure about his neighbours; time and experience in the work will remove this feeling no doubt. There should, I think, be more direct communication between the health officers on matters affecting their duties. In this way there may be fostered a conciliatory spirit and due consideration for the slips of others. It is, for instance, not edifying for Colony B to excitedly condemn Colony A because the health officer of the latter had inadvertently let a case of small-pox embark on a steamer and so arrive in an infectious state at B. Rather should the attention of Colony A be quietly drawn to the incident, and condemnation be deferred until the facts were investigated.

With regret must it be said of the medical profession that we are not all actuated by a wide reaching altruistic spirit. Some doctors, it is true, in the West Indies act in ignorance of the importance of complete and early notification in modern preventive medicine. Others, again, are ignorant of the aims and requirements of our quarantine system. Among such we find a hesitancy, without actual dishonest intent, to convict their own Colony of the crime of infection.

Again, because of the unpopularity of notification, especially with the mercantile class and the press, it is to be feared that some private practitioners knowingly suppress the truth about cases of infectious disease. There is less chance of government medical officers doing this, and in the smaller Colonies, where there are usually none but government doctors, there is little temptation to this want of candour.

One hears of instances where the medical attendant has said to the patient's friends: "This is what they are calling yellow fever,

but I don't believe there is any such thing here." The family is pleased to have been spared the fuss, and perhaps expense, of preventive measures which they do not understand and do not believe in. This doctor is likely to be called in similar cases, rather than the troublesome fellow who insists on fumigation and isolation. The conscientious medical man is almost invariably looked upon as an enemy of his country, and openly abused as such in the press.

Every West Indian will admit the truth of the above remarks as applied to Colonies other than his own; many will confess they know of cases even in their own Colony which were spoken of as suspicious at the time, or which subsequent events made suspicious, but were never notified as infectious.

So general is the feeling that full notification is usually withheld, that even when the medical officers of an infected Colony were using extra diligence to discover cases, and were being abused locally for so doing, rumours were circulated in an adjacent Colony, without a shadow of justification, that cases were being suppressed.

A more charitable trust is required between Convention Colonies, and grounds for such trust must be secured by rigorous enforcement of notification under Public Health Acts, which should, moreover, be as far as possible similar in effect. A notification law has actually existed recently in a Convention Colony which was intended to prevent undue and hasty notification. The fear evidently was, not of the disease, but of its notification to other Colonies. Such legislation does not increase mutual trust among the Colonies.

We have already mentioned that the admission of infection is extremely distasteful to the mercantile section of a West Indian community. Where there is much trade with non-convention places infection certainly does bring with it much of the disadvantages of the old quarantine methods as still applied by non-convention countries. The anticipated loss of business with such countries seems to the merchants of more importance than the obligation to confess infection. This is quite evident in the press. It is, of course, most short-sighted, for an unadmitted infection is the more apt to develop into an epidemic that cannot be concealed, and in the end the Colony suffers quarantine much longer than it need have done.

We are hardly justified in accusing the mercantile class of a selfish disregard for the life and health of the masses. It is natural that the laity should think less of public health than of

every-day affairs, and so permit commercial interest to blind them to the existence of a mild infection, which the sanitary experts regard as a grave danger. More than once has it been seen that health boards, composed chiefly of merchants, have retarded the machinery of notification and prevention.

It is therefore doubtful whether at present such boards can serve any useful purpose. They can only act correctly when they follow implicitly the guidance of the medical experts. Hence, if there are experts appointed to decide issues and carry out measures the lay health or quarantine board has no place. It is undesirable that lay boards should at all control health officers or be able to influence their actions. As long as mercantile interests are allowed to interfere with such purely technical matters as quarantine and public health, and the public opposes or discourages early notification, so long will medical practitioners be tempted to want of candour, and the distrust between the Colonies be perpetuated and justified.

Time and experience will teach the public that it is more prudent to welcome the early notice of an infectious disease, and that if a mistake is sometimes made it is better for it to be on the side of over-precaution.

It does not harm anyone to sleep under a mosquito net, even if he has not got yellow fever. The credit of a place is not damaged by the reported occurrence of an infectious disease, which is afterwards disproved or promptly stamped out. Rather is outside confidence strengthened by the sight of over-precaution.

This policy, too, will pay in our dealings with non-convention places, for as they recognize our sincerity and earnestness in managing quarantinable diseases, they will trust our statements, rely on our measures against exportation of disease, and treat us more liberally and rationally in consequence.

In conclusion, it may fairly be contended that the two main causes of our dissatisfaction with quarantine in the West Indies are the narrowness of sphere of the Convention and the uninformed and unthinking attitude of the public, especially the mercantile class, and the press. With regard to the former it is not for a private individual to insist dogmatically on a course which is of wide and international concern. But I am convinced that the extension of the Convention is the solution of the quarantine difficulties of the West Indies.

With regard to the public the cure must be left to time and education. But in the meanwhile it may be well for the Colonies

to consider whether it is not possible or desirable to take from the lay public the power of interference in a strictly technical matter like quarantine, to leave the health officer freer of control, even by Government, so that the management of quarantine may be released as far as possible from insular prejudices and commercial considerations.

## SOME NOTES ON WEST AFRICAN CURRENCY.

Christopher Columbus discovered America in 1498, but from all accounts he visited Sierra Leone and the Coast of Guinea in the course of earlier voyages. The Portuguese, however, are credited with having first discovered and explored the West Coast of Africa in 1482, forts being built by them at Elmina and in Angola soon after that date. No English traders appear to have visited the West Coast prior to 1544, but, during the seventeenth century, most of the maritime nations of Europe had established forts or factories there, from which slaves were supplied for the West Indies and America, as a sequel to the discovery of these countries. In 1808, and the years succeeding, all the nations concerned agreed to put an end to traffic in slaves, and the importance of the West Coast for a time diminished in consequence.

In 1787 the Peninsula of Sierra Leone (Lion Mountain), the port of which is named Freetown, was ceded by the native chiefs to Great Britain as an asylum for the many destitute negroes then in England, and in 1791 the Colony was handed over to the Sierra Leone Company, the object being symbolized by the device on the reverse of the coins struck in that year by the Company, viz., a black hand clasping a white one. Proofs of these coins, in capital preservation, are at the present time exhibited by the Bank of British West Africa, 17 Leadenhall Street, London. In 1807 the Colony was retransferred to Great Britain.

The Royal African Company held part of the Gold Coast Colony from 1667, being succeeded by the African Company of Merchants from 1750, and in 1821 the Colony was merged in the West African Settlements, under the Crown, in which Lagos was included in 1866. In 1874 the Gold Coast, including Lagos, was constituted a separate Colony, this arrangement existing until 1886, when Lagos became a separate Colony, only to be merged in the Colony and Protectorate of Southern Nigeria in 1906.

The Gambia was associated with Sierra Leone from 1807 to 1843, when the Colony of the Gambia was created, to be constituted a separate Government in 1888.

The history of the currency of these Colonies up to 1874 was, therefore, practically that of Sierra Leone.

In the early years of the nineteenth century the position of the currency of the West Indian, West African, and indeed most of the British Colonial possessions, proved an exceedingly complex and difficult one. The foregoing sketch of the early history of West Africa is sufficient to show that importations of coin from many different countries must have taken place, and in 1816, when the principles of the metallic currency of the United Kingdom were finally settled on the present basis of gold monometalism, the Imperial Government began to turn its attention to the deficiencies of Colonial currency, and in 1825 an attempt was made to introduce British silver coinage throughout the British Colonies.

In common with other Colonies, the Spanish dollar (or "piece of eight" reals) was the principal coin circulating in Sierra Leone and the—then associated—Colonies of the Gambia, the Gold Coast and Lagos, the value in commercial transactions being 5s., but for issue to troops 4s. 8d., until 1825, when, by Treasury Minute, it was altered to 4s. 4d. The prevalence of that coin and its quarters (cut frequently into five parts, which caused the Government to obtain a stamp marked W.R., surmounted by a crown, for the purpose of stamping legal quarters) made it impossible for British coin to be successfully introduced for some years. It is interesting to note that, about 1835, the Sierra Leone Government suggested that "a separate small coinage, which may serve generally for the English settlements in the West of Africa," should be issued, and in the following year £1,000 of 3d. and 1½d. pieces and £500 in pence and halfpence were issued by the Treasury. A year or so later 83,076 "cut quarters" were shipped home from Sierra Leone to be sold as bullion, and in January, 1839, on receipt of £2,500 in shillingā, £2,500 in sixpences, and £2,000 in three-halfpenny pieces, the Governor of Sierra Leone, by proclamation, demonetised all cut monies or cut parts of dollars.

By orders in Council of 10th June, 1843, certain regulations established in the West Indies were extended to the West Coast of Africa, and exchange values of certain coins were fixed, the sterling value of the Spanish, Mexican and South American doubloon being 64s., the 20-franc piece 15s. 10d., the dollar of Spain, Mexico, etc., 4s. 2d., and the 5-franc piece 3s. 10½d. Later the American Eagle, at 41s., was included. The "Maria Theresa," or Austrian dollar of 1780, which was carried to many

parts of Africa, from the Nile Valley and Tripoli, although chiefly as an article of barter, was probably not found to any great extent at West Coast ports. Within recent years, however, replicas were struck for export to Northern Nigeria, but hardly as a form of currency. As in the case of British silver to-day there was no limit as to tender of silver coins, with the result that gold was practically never seen. In 1877, as a result of the depreciation of the gold price of silver, the silver dollar, worth barely 3s. 8d., was largely imported by merchants and speculators into the Colony of Sierra Leone, where its legal tender value was 4s. 2d., and English coin was therefore rare. This position was dealt with in 1880 by an Ordinance being passed under which the dollar ceased to be a legal tender. The Colonial Government, however, received the demonetised coin for a stated number of days at its old value, the amount so received being about £26,000.

In the year 1880 the 5-franc piece was demonetised in the Gold Coast Colony and Lagos, but, although the question was considered in 1880, and again in 1893, the 5-franc piece of the countries forming the Latin Union (France, Belgium, Italy and Switzerland) continued, and still continues, to be legal currency in the Gambia and Sierra Leone, at an official exchange of 3s. 10½d. The title "dollar" is frequently applied to the 5-franc piece in these Colonies at the present time.

As has been stated, the system of currency in Sierra Leone was nominally that of the Gold Coast, but the position in the latter Colony was complicated by special circumstances. Rock gold or nuggets and gold dust (which in earliest records is referred to as a considerable article of trade) passed current at 72s. per ounce, the ounce being subdivided into sixteen "Ackies" (4s. 6d. each) and each Ackie into six "takeos" (9d. each). These names "ackie" and "takeo" are found on coins, bearing on the reverse, "Free trade to Africa," issued at the end of the eighteenth century by the Royal African Company. Rock gold and gold dust were demonetised in 1889, owing to practices of adulteration. In addition to the gold dust currency, in which medium the Dutch Government (which finally ceded their forts to Great Britain in 1872) paid salaries, etc., from the year 1846, the Dutch silver coin of 2½ florins, or guilders, appears to have passed as a dollar, while sub-divisions of that coin also circulated. When, however, the value of silver fell, these coins, and also Mexican dollars, were largely imported, until the passing of the Ordinance of 1880, which restricted the currency, as in the case of the neighbouring Colony of Sierra Leone.

Advantage was also taken of the fall in the gold price of silver in 1879 in the case of Lagos, to which Colony large shipments of dollars were effected at a profit of over 10 per cent. The Lagos Government balance on 31st July, 1879, amounted to £10,920, of which no less than £9,200 consisted of Mexican, Peruvian, Chilian and Brazilian dollars.

The Gold Coast Demonetising Act of 1880 embraced Lagos, but the ten days' notice given does not seem to have been taken full advantage of here, as much hardship was occasioned to holders of dollars, who, from the 21st May, were unable to pay their duties in that form, or to exchange the coins at the value at which they had been received.

British silver coin, notwithstanding the opposition of other forms of currency, was then being exported to West Africa in increasing quantities. Pre-Victorian coins were refused, in the belief that on the demise of the Crown the coins of the reign cease *ipso facto* to have legal currency, and when the Victorian Jubilee coinage was introduced a Government notice had to be issued on the subject of the change. There was not much general difficulty, however, in getting the natives to accept the present King's Head coins, and in certain districts objection is now expressed by the natives to early Victorian coinage. From 1876 to 1880, according to statistics compiled in 1899 by the Manchester Chamber of Commerce, over £200,000 had been shipped to West Africa in British silver coin, a figure which increased, in the period from 1891 to 1895, to £750,000.

In the year 1892 the first West African Bank was established at Lagos—the African Banking Corporation, Ltd.—and, under an agreement entered into with the Colonial Office, the issue of silver coin from the Royal Mint, for shipment to Lagos, was confined to that institution. In 1893 the Corporation retired from Lagos and, in the following year, the Bank of British West Africa, Ltd., was formed, and inherited the responsibility for the control of the silver currency, their position as the Government Bank being extended in subsequent years to the Colonies of the Gambia, Sierra Leone and the Gold Coast. Thus was established a necessary central control, which, so far as possible, supplies the currency requirements of one Colony from the surplus silver coin of another, thereby preventing unnecessary shipments of a token currency from England. Where the Bank of British West Africa was established the prevalent barter system rapidly disappeared, and the demand for British silver currency increased. The nominal or face value of new British silver (which until a few years ago had a greater purchasing value in native markets than used coin) shipped to West Africa from 1894 to 1903 amounted to no less than £2,856,000, or an average of over

£190,000 per annum. No coin of higher value than the florin is sent. Of that sum £822,000, or nearly 6s. of each pound exported, was repatriated and placed into circulation at home during the same years—an onerous duty which previously entailed considerable expense to the Governments concerned. The total nominal value of British silver coin hoarded, converted into ornaments and in circulation in West Africa, is probably three to four million pounds sterling at the present time.

Bronze coin was also shipped from England to the West African Colonies, but probably in small quantities only, and in Lagos, some years ago, it stood at a discount of 10 per cent. as compared with silver coins. For instance, three bronze pennies would only exchange for  $22\frac{1}{2}$  strings of cowries, whereas a silver threepenny bit commanded 25 strings. A requisition was received from Sierra Leone for a quantity of copper coins, so far back as 1822, but was not complied with. The demand for a medium of exchange in West Africa for small native transactions was formerly supplied by cowries (a small shell imported from East Africa) and, particularly in the Niger district, brass rods (value about  $2\frac{1}{2}$ d.), Manillas (a kind of horseshoe of copper, valued at about  $1\frac{1}{2}$ d.), and copper wires ( $\frac{1}{8}$ d.) The fluctuations and inconvenience of the most popular of these, cowries, is shown by the fact that the "head" of 2,000 varied in value from 6d. to 2s. 6d. in the different Colonies.

It has already been noted that a Special Subsidiary coinage was suggested for West Africa about 1835, and the larger question of replacing British silver coinage in West Africa by a Colonial silver coinage was, in 1899, referred by the then Colonial Secretary, Mr. Chamberlain, to a West African Currency Committee under the chairmanship of Sir D. Barbour. This enquiry was made partly with a view to giving the Colonies the considerable minting profit which the Treasury declined to share, and it is interesting to note, in this connection, that the adoption of a special silver coinage is now under consideration by the Australian Government. The obvious advantages of the Imperial silver currency for the Crown Colonies of West Africa were generally recognised by the Committee referred to, although recommendations were offered in the event of a special coinage being adopted, and the question of a subsidiary coinage was answered by certain findings as to bronze and nickel coins. It was stated that British bronze coins, while circulating freely in the Gambia and Sierra Leone, were refused by the natives on the Gold Coast and in Lagos and Southern Nigeria. Statistics appear to show, however, that this objection was gradually being overcome, as the shipments of bronze coin by the Bank of British West Africa in the year 1907 to Lagos amounted to £3,680

nominal value, and to the Gold Coast Colony £1,100. The Reports of the Gold Coast Colony for 1907 and Sierra Leone for 1908 call attention to the marked increase in the use of bronze coinage.

No immediate action took place as a result of the enquiries of the Currency Committee, but, in 1906, by Royal Proclamation, the Nigeria Coinage Order came into force, and established for Northern and Southern Nigeria a special subsidiary nickel coinage of two denominations—one penny and one-tenth of a penny. These coins, which are legal tender, as in the case of bronze coins, for payments up to one shilling, have a hole in them to allow of stringing together, but do not bear the effigy of the Monarch. They are now in circulation, and the result of the issue will soon be seen. As the coins bear the inscription: "Nigeria—British West Africa," the omission of the first word would permit of their circulation in other West Coast Colonies, and thus maintain an interchangeable currency, although this might be more fully achieved by an adherence to British bronze coins, in respect at least to the penny piece.

Southern Nigeria is also taking the lead, amongst West African Colonies, in the matter of a Government note issue, which, early in the present year (1909), was consented to by the Treasury and Colonial Office. There is no doubt that a need for a paper currency indicates a progress in the development of a Colony, and the experiment, when started, will be watched with considerable interest. The value of the notes will probably be £20, £10, £5, and £1, and, if the scheme provides for their immediate convertibility throughout the Colony, the avoidance of some of the constant movement of coin, and the provision of the means of temporarily increasing the currency, should result.

That there is a demand for a higher denomination of exchange than silver coins provide, is undoubtedly a fact, and, to meet this, British gold coins, hitherto seldom met with to any extent, are now being exported to various West African Colonies by the Bank of British West Africa, Ltd. Perhaps, as in the case of the special nickel currency and British bronze coins, a postponement of the suggested note issue might show that it was rendered unnecessary at present by the increase of gold in circulation.

LESLIE COUPER.

[It is impossible to publish these notes without giving full acknowledgment to that standard work, Chalmers' "Colonial Currency," from which much information has been obtained and quoted. L. C.]

## REVIEWS AND NOTICES.

A History of the United States and its People. By E. M. AVERY. Vol. III. (*Burrows Brothers Company, Cleveland, U.S.*)

THE period which this volume covers, 1660-1745, was one of continual unrest caused fundamentally by economic struggles. It was the accepted policy of the time that the chief mission of a colony was to feed its mother country. This was the object of the first Papal Bulls regarding the New World and of the charters of the early trading companies. The English colonies were to furnish raw materials in exchange for English manufactured goods. The bargain, however, was by no means altogether one sided. The Navigation Acts kept out foreign ships for the benefit of English bottoms, but on the other hand they gave a practical monopoly in many respects of the English market to the colonial planters. Nor did the restrictions intended to keep the colonies to planting and prevent them from manufacturing bear very grievously on them. The staple industries found a good market in England, where they had an advantage over foreign places by entering largely duty free. The policy in fact succeeded with the places which were content with plantations. The West Indies exported tropical products and made no attempt to rival English industries. The restrictions therefore on the whole affected them little, and the result was seen in their steadfast loyalty. In America it was different. The Prohibition Laws were an obvious and irritating interference, and the colonists, rightly or wrongly, concluded that they had the losses and the English manufacturer the gains of the system. Such a feeling is sure to arrive from a compulsory arrangement. But the broad fact remains that as business ventures the English colonies flourished, while the French did not. The greatest mischief which the policy of restriction did was elsewhere—in Ireland. It forced idleness upon a population of artisans, and the result was an

exodus. "Thirty thousand Protestants," Froude observed, "left Ulster for a land where there was no legal robbery." (Philadelphia.)

This line of cleavage was supplemented by others. The struggle between Cavalier and Puritan, the party of prerogative and the party of the people's rights, was repeated in the colonies with chaotic results at times, but with the steady growth of the Puritan party. In Carolina no Governor could long support his authority, and at one time so violent was the contention that no laws were passed for ten years or more. Massachusetts from an early period maintained a position of quasi independence. A benignant letter from the King in 1661 was answered by a declaration of rights, including the right to reject any Parliamentary or Royal imposition "prejudicial to the country and contrary to any just act of colonial legislation." In 1664 things had gone so far that men-of-war were sent from England to bring the New England Colonies into subjection. But the mother country had more serious matters to attend to, for in the following year the Dutch entered the Thames and burned English men-of-war at Chatham and the great Plague broke out in London. In this trouble Massachusetts behaved handsomely. It provisioned the West Indian fleet and rendered other service "by way of humble thanks to His Majesty for the many and continued expressions of his tender care and fatherly respect to this, his Colony." Evidently the opportunity for a sarcastic thrust was too tempting to be neglected. Afterwards the struggle with the Crown went on till in 1684 Massachusetts charter was adjudged to be forfeited. But this was of no great consequence at the time as the revolution in England followed shortly afterwards and changed the position. There was, in fact, a simultaneous revolution in England and in America. "On both sides of the Atlantic," Mr. Avery observes, "the people and popular rights were gaining ground in their long controversy with arbitrary rule and Royal prerogative." But the rise of Parliamentary power in England did not end the conflict. In the words of Mr. Goldwin Smith, "Royal tyranny ceased but Parliamentary tyranny began." The strengthening of the English mercantile system remained the object, and dictated restrictions on the Colonies.

The detailed history of the American colonies, set out in vivid style by Mr. Avery, shows clearly enough how steadily events and ideas marched almost from the commencement towards the eventual declaration of independence. The necessities of England were dictated by long and exhausting wars and it was reasonable to expect some form of assistance from the colonies. But to put this in the shape of restrictions on American trade for the benefit of English trade invited opposition. The idea of friendly combination for the common welfare is in these annals conspicuous by its absence and the art of diplomacy for the purpose of mutual

understanding unknown. The result was not only political separation but intellectual alienation. "For nearly a hundred years American historical writers habitually characterized the British colonial policy of the eighteenth century as malicious and tyrannical, but said little about what that policy really was. Meanwhile English writers were accusing their American brethren of partisan unfairness, but giving no clear idea of the system they were trying to defend."

This volume, like its predecessors, contains a remarkably full collection of portraits, maps and sketches, and is a pleasure to peruse, both from its matter and its artistic embellishments.

---

**Essays in Politics.** By A. MACPHAIL (*Longmans, Green & Co.*)

There is a good deal of plain speaking in this book, and it is refreshing to find that the writer takes a cool and impartial view of the operations of British diplomacy on behalf of Canada. Visitors to the Dominion are often on some occasion or other confronted with the representation that the negotiations conducted by the home Government with the United States have invariably failed to do justice to Canada. The explanations given in this book amply suffice to show that the situations which had to be dealt with were difficult and dangerous, and that the settlements arrived at were on the whole as satisfactory as circumstances permitted. There came a time when the Canadian authorities themselves took up the function of negotiating, but the result is commemorated by the historic words of Sir Wilfrid Laurier: "There will be no more pilgrimages to Washington."

Mr. Macphail's leading proposition, in the discussion of Canada's position, is that Canadians are paying more per head of population for the general good than England pays. In new countries the work of making life and property safe, and opening up communications has to be done *ab initio*, and the taxation is necessarily heavier for these purposes per caput than in an old country, where much of the work has been done. The inference is indicated, though not put definitely, that Canada may be reasonably exempted from the duty of assisting in the defence of the seas. We doubt whether Canadians generally would adopt this agreement. The difficulty is not really that Canada cannot afford to pay, but that a payment without a direct voice in Imperial policy could hardly be justified to the people of the Dominion. The solution of the matter will no doubt, as shown by the result of the recent conference, be on the lines of the development of local defences.

### The Official Year Book of the Commonwealth of Australia.

The second issue of this publication has made its appearance. It contains detailed statistics for every year since the establishment of the Commonwealth (1901) and a considerable amount of corrected statistical information for the whole period since the first colonization of Australia. But the Year Book is much more than a collection of tables and diagrams. Different aspects of the life of the Commonwealth are dealt with historically in special articles, and it has been arranged that new subjects shall be taken up and treated in this manner in future issues of the annual. In conformity with this plan, many of the articles which appeared in the first issue of the Year Book are now reduced to synopses, while much fresh matter has been introduced. The volume reflects much credit on the Federal Bureau of Census and Statistics, which is responsible for its production.

---

### The Canadian Annual Review for 1908. (By I. CASTELL HOPKINS. *Annual Review Publishing Company, Toronto.*)

This number keeps up the high reputation of the series by the full and clear way in which it sets out the doings of the year. It is no light task to chronicle the parliamentary proceedings, the economical progress and the social advance of so vigorous a country; but Mr. Castell Hopkins never fails to give the sense of completeness and vividness. The part which the Dominion plays in the politics of the Empire is dealt with prominently.

---

### Notes on Dominica and Hints to Intending Settlers. (By SIR H. HESKETH BELL, K.C.M.G., revised by W. DOUGLAS YOUNG, C.M.G. *Advocates Co., Ltd., Barbados: 6d.*)

In former generations this country sent out a goodly number of planters to the West Indies, but subsequently misfortune of one kind and another interfered grievously with the attractions. The islands have, however, in recent years entered on a new phase of prosperity which is based on careful study, and is therefore likely to endure; and the opportunities which are now held out to settlers with a moderate capital and a liking for agricultural life—such as this country can still supply in plenty—are well worth examination. This little book gives the case of Dominica. That the island is on the up grade is sufficiently clear from the fact that its trade has much more than doubled in the last decade. The products are of a very varied character, and it is not necessary, or well, for a grower to limit his work and interest to any one of them. It is desirable that a man intending to go out with the object of starting a plantation should find a companion and partner, and that before any land is taken up some months' experience of the working of estates should

be acquired. In Dominica this could be easily arranged. "There are several planters in Dominica of good birth and breeding who are prepared to let men of their own class stay with them for a few months. So far, there has been no system of taking regular pupils, nor is any premium asked. If a man is a gentleman and of congenial tastes, there are several owners of estates in the island who would be willing to teach him what they can in the way of agriculture, and board and lodge him for a couple of pounds a week."

The following account shows the prospects which are open to a settler with a capital of about £3,000.

"The island is estimated to contain 291 square miles. Almost the whole of the land along the sea-board is private property, and is laid out in a succession of cacao and lime estates. Up to about nine years ago, the whole of the interior of the island, though known to comprise fertile land suitable for most kinds of tropical products, remained practically untouched. This neglect was entirely due to the fact that the interior, owing to the absence of roads, was inaccessible. Thanks to an Imperial grant, a large area of these lands has been made available and a trunk road called the 'Imperial Road,' 18 miles in length from Roseau, has been constructed right into the heart of the island. Considerable blocks of the Crown lands, adjoining this road, have been taken up, and several promising plantations are being developed by Englishmen who have recently settled in the island. The 'Imperial Road' opens up a large extent of virgin land suitable for a variety of products. Districts having an altitude varying between 1,000 and 3,000 feet are well adapted for the cultivation of oranges, grape-fruit, nutmegs, rubber, cardamoms and other spices, while the lands that lie below 1,000 feet are considered to be more suitable for cacao, limes, pine-apples, etc.

"It is estimated that the Crown lands comprise about 100,000 acres. They are sold at an upset price of 10s. per acre. The payment of the purchase money for blocks exceeding 100 acres is spread over three or four years, if desired. The survey fees are extra, and average 2s. 6d. an acre for small blocks. The Crown lands for the most part consist of ridges and valleys; the slopes are admirably suited to tropical agriculture, and in the centre of each valley a stream of excellent water is usually found.

"It may be taken as a fair average that to purchase, clear and plant 1 acre of virgin forest will cost about £7. It will then cost £3 a year to keep that acre in proper cultivation until it yields a crop. Though in some cases, cacao, limes, budded oranges, etc., may bear when three or four years old, no profitable return can be expected in that time, and it would be advisable to reckon that £3 a year would have to be spent on cultivating

that acre for seven years, though some return may be expected before that time, more especially in the case of limes, which yield a return before either cacao or oranges.

"A prudent, temperate and practical man with a capital of about £3,000 should be able to take up 200 acres of Crown land in a selected area, and to clear, plant, and cultivate 50 acres of it for a period of seven years, at the end of which he should be possessed of a valuable estate yielding a steadily increasing income. As his clearing of 50 acres begins to give some return before the seventh year, he should utilize that return in the further development of the 200 acres.

"Cacao trees should begin to bear at the end of the fourth year, but would not be in full bearing until about the eighth year. Planters should therefore not look for nor calculate upon, any return from their cacao until it is seven years old. Limes commence to bear in their fourth year and should give a good return when six years old. Budded oranges will bear in five years, and coffee in four years. An acre of cacao or limes, seven years old, should yield a net profit of from £10 to £15 per acre."

A general idea of how a settler with a capital of about £3,000 might establish himself in Dominica may be gathered from the following statement:—

	Cacao.	Limes.
	£	£
Purchase of 200 acres of Crown land and fees ...	130	130
Clearing, planting, and cultivating 50 acres ...	1,400	1,250
Cacao house and drier ... ..	150	—
Mill, two-tayche battery, and buildings ... ..	—	300
Small dwelling house and out-officer ... ..	250	250
Labourers' houses ... ..	100	100
Living expenses for 7 years, including groom and house servant, at £100 per annum ... ..	700	700
Incidentals at £30 a year for 7 years ... ..	210	210
	<u>£2,940</u>	<u>£2,940</u>

**Report on Plague in the Gold Coast in 1908.** (By W. J. SIMPSON, M.D., C.M.G. *J. & A. Churchill, 2/-net.*)

The outbreak of plague in the Gold Coast was remarkable for the large proportion of pneumonic types. Many of the cases terminated with appalling suddenness. The constitutional symptoms were here of slight nature and in fact the history was sometimes nothing but sudden death.

The circumstances of the outbreak, Dr. Simpson states, seem to indicate that the potentialities of plague to reproduce epidemics

corresponding in their nature to those of the 14th century still exist under favourable conditions, that the spread of the disease may be readily facilitated by pneumonic cases with undefined symptoms, and with such epidemics do not require for their propagation or extension either rats or fleas, though they may be reinforced and maintained in a locality by rat infection. It was demonstrated that the Danysz Virus generally requires to be exalted before it can be acted upon, and that it can be exalted if sufficient care be taken. This report sets out in detail the measures taken to suppress the disease in Accra and to prevent it from spreading. Haffkine's Prophylactic was used by over 31,000 persons in the colony. A land cordon was drawn round Accra, and no person was allowed to pass out unless he had been inoculated at least a week before.

## BUSINESS NOTES.

### Armoured Cement Poles.

(LETTER TO THE EDITOR.)

It may be of interest to the readers of the Colonial Office Journal generally, and to the Works Departments of the various Crown Colonies in particular, to know that costly iron poles, liable to rapid oxidation and consequent failure can now be replaced by a much cheaper and practically indestructible pole of armoured concrete.

For the distribution of electric power, overhead cables are now almost generally adopted. These lines in Lagos, together with the telephones in Calabar, and the gradually increasing mileage of telegraphs in S. Nigeria, now aggregate many hundreds of miles. Considering the great capital outlay for such work it is obvious that the reliability and the cost of upkeep of these lines must become a matter of great importance.

The present system of iron poles in no way answers all the requirements of reliability and certainly not those of durability, requiring, as they do, constant scraping and painting to prevent the rapid oxidation that takes place in a climate such as West Africa.

Reflection must lead to the conclusion that an indestructible material, the upkeep of which would be very low or nil, such as ferro-concrete, is what is required, providing the cost of such material is not commercially prohibitive.

During my last tour in Calabar I succeeded in designing and making most excellent fencing and gate posts of this material at the very low cost of one shilling and eleven pence per post of seven feet in length, and these were capable of resisting a ton strain without fracture when fixed three feet in the ground.

The making of poles to carry the overhead wire for the proposed "Qwa-Falls" power scheme next attracted my attention, and

experience showed that solid poles on the principle of the seven feet posts would be much too heavy and cumbersome; on the other hand, cast iron bases, with wrought iron top lengths would, I found, be very expensive, besides being liable to collapse from internal oxidation.

To make a suitable hollow pole by casting around a frame work over a core was next attempted but without success; but this problem now appears to be solved by the use of the Siegwart pole, brought to my notice by Messrs. Preece and Cardew.

Mr. Siegwart's invention, by doing away with any external mould, overcomes the difficulties that have thus stood in the way of tubular reinforced concrete construction, and by its means hollow poles, pipes, piles, &c., of any length or strength can be made with the certainty that the reinforcement, either longitudinal or spiral, will be embedded with absolute precision in the exact position required even in the thinnest walls of concrete which may be necessary.

The process of manufacture is entirely new and ingenious, the main principle being that concrete can be wound in a ribbon helically round a hollow core, completely surrounding longitudinal reinforcing rods previously laid along the core, and keeping them in the exact position desired. Immediately after the concrete is so woven, wires of such strength as may be required are also wound spirally round the outside of the longitudinal rods and embedded in the concrete. The concrete is uniformly compressed by weighted rollers to an extent impossible by any system of hand ramming, thus rendering the whole mass dense, compact and homogeneous. A coil of webbing is wrapped round the concrete to keep it in place until it is set. The core, which is collapsible, can be removed after 12 hours, and the webbing after 3 or 4 days.

The average thickness of the walls is from 1 to 2 inches, according to the diameter. On the whole the poles are uniform in shape, and vary only in the thickness of the walls and diameter according to their length and the load they have to bear.

They consist in detail of a skeleton of longitudinal steel or iron rods tied together by a spirally wound strong wire, and the coat of concrete in which the skeleton is embedded—this same process is applicable to drain pipes up to 48 inches in diameter.

The pole, or pipe, is perfectly finished in the machine, needing only a short time for setting and drying. The whole process is quick, economical, and warrants a high class concrete of great density and homogeneity.

I have watched the making of these poles and pipes at Messrs. Cubitt & Co., Gray's Inn Road, London, and I consider the process is of the greatest interest to the technical world, and more especially

to our tropical Crown Colonies, where the prevailing moist atmosphere is so destructive to anything in the shape of Wrought Iron or Steel.

Yours, &c.,

I. T. HANKINS, A.M.I.C.E.,

Sen. Prov. Eng. S. Nigeria.

P.S.—As the foregoing was too late for your July issue, I wish to say that since writing it I have inspected with several other Engineers the new and improved plant which is automatic in all its adjustment of thickening and tapering. This machine, now at Messrs. Cubitt's, Gray's Inn Road (eventually to be removed to "Grays"), is well worth a visit from Colonial Engineers interested in this class of work. I have already arranged for several of the "Inspectors of Works" of S. Nigeria to become conversant with the details and general working of the machine with the idea of eventually making our own poles and pipes in the Colony. (I.T.H.)

---

### Dredging the Lagos Bar.

The twin-screw pump hopper dredger, "Sand Grouse," for Southern Nigeria, has been built by Messrs. W. Simons & Co., Ltd., of Renfrew. It was launched on 8th June and tried over the sand banks in Morecambe Bay. About 2,070 tons of sand were pumped with the hopper in 54 minutes, and about 2,000 tons were emptied through the valves in 27 minutes. The average speed of the vessel with and against tide was  $10\frac{1}{2}$  knots per hour. The light draught is 7 feet 3 inches forward and 10 feet 4 inches aft.

The present dredger, the "Egerton," has done good work, though working very intermittently, and vessels of 14 feet draught can now cross with much greater facility than vessels of 10 feet did in 1904. This improvement has been effected without any assistance from the Eastern mole, which has only just passed the line of the foreshore. The further extension of this mole will, however, facilitate the work of dredging, and as the "Sand Grouse" has a dredging capacity 50 per cent. in excess of the "Egerton," a further improvement may reasonably be expected. Several steamers trading direct to Europe have already entered the harbour. In June, the "Teneriffe" (Elder, Dempster and Co.) crossed the bar and came into the river; it is said there was more than 20 feet of water. Continued improvement will lead to very important results in the shape of increased trade. When a satisfactory draught has been secured it may be possible to levy tonnage dues. The Government gets no return at present for the dredging done, but would have good ground for claiming some when the draught for steamers is permanently reduced to, say, 15 feet, which means a depth of 18 feet.

Many cargo steamers from Europe could then regularly cross the bar and enter the harbour partly laden. Such a draught is in excess of that at Opobo, which is served entirely by ocean-going steamers; the shipment of palm oil and kernels alone then amounted in 1907 to 38,000 tons.

The contract price for the "Sand Grouse" was £86,065.

A twin-screw hopper barge, the "Mole," has also been constructed for Southern Nigeria, and left Port Glasgow on 24th July. The light draught is 4 feet 4 inches forward and 6 feet 5 inches aft; at the trial in stiff mud it was estimated that 90 tons of spoil were deposited in the hopper in 30 minutes.

A type of dredger which has been used on the Panama Canal is being tried by the Soudan Irrigation Department on the Blue Nile. It is constructed to manipulate one bucket about 7 ft. deep and 4 ft. diameter, capacity about 5 cubic yards. This is lowered from a powerful crane, which projects forward and scoops the bucket along the bottom, raises it, and swings it to the side. The vessel is fitted with three legs, one at each corner of the fore and one in the centre of the stern, which are lowered till they rest on the bottom; in this way the vessel is made stable, and the stern leg swings fore and aft so as to take the backward thrust of the bucket.

At Forcados a second floating dock has been ordered by the Nigerian Dry Dock and Engineering Company, capable of lifting steamers up to 8,000 tons. There is no other dry dock in British territory between Gibraltar and the Cape. Some 30 native apprentices are being trained at the engineering works of the Company, and the results of this policy will be very interesting, as it would greatly help railway construction and management if it were found practicable to train a considerable number of natives for the work.

---

### Motor Transport.

From the blue-book on "mechanical transport in the Colonies" (Cd. 4,589) it appears that Crown Colonies in which light motor cars and taxicars are suitable are Barbados, Bermuda, British Guiana, Gold Coast, Southern Nigeria, Straits, Ceylon, Antigua, Grenada, Trinidad, Uganda.

In Southern Nigeria a motor road service was adopted in preference to a light railway between Ibadan and Oyo (33 miles), on a road without foundation but with good surface. Paraffin is exclusively used except for starting up, the price of petrol being prohibitive. The service is successful, and there can be no doubt that light motor lorries will soon secure a great import of transport that now goes on head. But there must, of course, be a fairly hard road, though not necessarily "metalled" if the character of the soil is such as to give a good surface.

### Singapore Fire Brigade.

A powerful new motor fire engine has just been supplied to the Singapore Fire Brigade by Messrs. Merryweather & Sons of London, and constitutes the third motor appliance built for this brigade by the same firm. It is driven by a 50-h.p. petrol engine, and comprises a fire pump, fire brigade tender, hose reel and fire escape, all embodied in one machine. The fire pump, which is worked by the same motor as propels the vehicle, delivers 350 gallons per minute, and will throw one, two, or four jets. The hose reel, which is carried at the rear of the engine, is detachable, and carries 400 feet of canvas hose, whilst a large quantity of hose and gear can be accommodated in the main box at centre. The fire escape extends to a total height of 50 feet, and can be detached for service in a few seconds. The whole machine, loaded with men and gear, can travel at 30 miles an hour on the level, and ascend steep hills at a good speed. With its capacity for instant turn-out, its great speed, and the novel combination of fire extinguishing and fire escape plant which it embodies, this appliance should certainly prove a valuable addition to what is undoubtedly one of the best equipped brigades in the East.

---

### Gas Engine and Cotton Seed.

An expert of the British Cotton Growing Association reports as follows:—

“A very successful experiment has been made in the utilisation of cotton seed and cotton seed cake for the generation of a gas to drive a 30-h.p. gas engine, which is used for working the mills and presses for the extraction of oil and production of oil cakes. This engine is run daily for 9½ hours upon the total expenditure of 6 cwt. of cotton seed cake, and it is said that with the employment of cotton seed before the oil has been expressed an even smaller quantity is necessary. By the use of waste seed for gas production all the machinery might be driven without the great expense of coal, and a new and important source of economy is clearly indicated.”

---

### Native Pottery.

An interesting experiment is being tried in Southern Nigeria in training young natives to make pottery at Ibadan, where there is suitable clay. For fuel wood and cotton-seed mixed have been tried, but the cost of cotton-seed being £3 per ton coal was practically not dearer. Wood and a few palm-kernel shells were then tried and found the most suitable. There is a great demand for the products.

---

**Silver.**

The present price of silver has disappointed some anticipations. The low figure is due to plentiful supplies, and the chief reason for them is the increasing output of Cobalt, which at present is adding from 25 to 30 million ozs. a year to the production of the world. The requirements for silver currency are growing all over the world, but no important change is likely to happen in the near future, as the Indian Government will probably be out of the market for a long time, and the Chinese trade position is uncertain. The excess of imports into China over exports diminishes year by year, and this fact explained the large stock of sycee held in the East by China (probably about £3,000,000) and in London (about £2,000,000). China is in fact at present gorged with silver, but as for the time being exports exceed imports, silver is the cheapest form of remittance, and the stock which is held as a cover against exchange is not likely to be put on the market while that continues.

---

**Oil Gas Lighting.**

By an error in printing the cost of oil, &c., per light per hour was put at p. 55 at 7d., this should have been .07d. Messrs. Mansfield and Sons, of Liverpool, inform us that they are inclined to doubt whether this figure is strictly correct, and would put it generally at .125 per 100 candle power per hour. The higher figure leaves the economical advantage of pure oil gas very apparent.

## RAILWAY NOTES.

## Cape.

The total earnings in 1908 amounted to £2,850,139 as against £3,469,936 in 1907, a decrease of 17·9 per cent. The loss after allowing payment of interest was £546,695. These figures are lamentable and indicate the lowest point of depression in the record of the lines. There are signs that things have since begun to improve and there is reason to believe that the worst has now been passed. The curtailment of expenditure by the De Beers Company, which affected the traffic seriously, was caused not by any local circumstance but by the heavy drop in prices. After having given full weight to all mitigating circumstances it seems impossible to avoid the conclusion that the position is economically very unsatisfactory, and that the case shows the necessity of carrying out a railway policy on well considered estimates of revenue and expenditure. Of 30 branch lines only one showed a net profit after paying interest on capital, and ten failed to pay their working expenses. The General Manager remarks, *à propos* of these losses on branch lines, that he feels sure that when the lines were authorised it was never anticipated by Parliament that they would do more than pay their way for many years to come. Probably a more optimistic view was taken at the time, but no doubt there was a disposition to allow losses in order to develop particular places and industries. The General Manager urges that "when the Railway Department is called upon to make sacrifices in order to support a particular local industry, the loss sustained in doing so shall be refunded to the Department from the general revenue of the Colony." This would be academically sound and fair to the Railway administration. But in practice it can hardly be expected that Government will drag losses into the light in this way.

A drastic step has been taken to increase the traffic. It appears that the principle adopted is that if the State provide railways the public must be compelled to use them. The particular case dealt with is that of ox-wagon competition. As to which the following statement is made:—

"During the year ox-wagon competition continued to adversely affect the receipts of the Midland and Eastern Systems, especially the latter, the transport wagon being much in evidence in the Eastern Districts.

"In my reports for some years past I have strongly advocated the introduction of legislation with a view to imposing a tax on wagons competing in districts served by railways, and I am pleased to say that Parliament has recognised the very serious nature of this competition, and during last Session action was taken in this direction, Parliament having approved the principle that when the State has provided means of transport with the money of the general taxpayer it is incumbent on the public to make use of the facilities provided.

"In order to avoid the infliction of any undue hardship on merchants who might be carrying heavy stocks, it was decided not to enforce the arrangement sanctioned by Parliament until the 1st March, 1909.

"It is hoped that the action now taken will relegate the ox-wagon to its legitimate sphere, that is, to act as a feeder to the Railways, and not as a competitor."

It was an awkward circumstance that the ox-wagon appeared to transport traffic to distant points, not only more cheaply, but often almost as quickly as the railway. Part of the explanation of this is that the railway authorities hold back consignments till they make up good loads. But there are other reasons, and the account of them is instructive.

"Comparisons have been drawn in the press, in many letters to Railway officers and in verbal statements, to show that the ox wagon transports traffic to distant points almost as quickly as the railway. It is almost overlooked that to begin with the kurveyor is not prepared to hire out his wagon for a small consignment as his rate of carriage is based on a full wagon load. The railway, on the other hand (with the exception of weights of 100 lbs. or thereabouts), conveys all goods traffic at a class rate whether a consignment consists of a few bags or a full truck load. Any comparison in time between rail and ox wagon transit when both the railway truck and the ox wagon are fully loaded is out of the question, but a similar comparison regarding a few light weight packages handed to the railway, and the full wagon load of the kurveyor is very often warranted.

"No railway can afford to send trucks direct to each point for which small quantities of goods are tendered for conveyance.

"It is only in holding back these consignments to ensure larger loads, and in concentrating the transshipment for various stations on certain centres, that an economical result can be achieved. The need for curtailment of expense in haulage justifies this procedure.

"If the public demand a quicker transit for these small consignments, the only course open to the Department would be to follow the system in vogue on the Continent and charge a percentage addition for quick transit on consignments of less than truck loads.

“Under certain circumstances, protracted transit of goods is unavoidable; for instance, goods traffic despatched, say, from a station at or near the coast, the goods being destined for a branch line where the traffic only permits a service of three trains per week, unless the goods arrive at the junction on a day when the train runs to the branch, a delay is bound to occur at the junction point. A delay might be caused if the connecting train for the branch is unable to take the whole of the load offering, and the surplus left over at the junction is insufficient to warrant the running of a special train; a further delay might occur through Sunday intervening. The most frequent cause of delay to merchandise of this description is caused through passengers, live stock and perishable traffic having preference in transit over ordinary goods.”

It is clear that circumstances of this kind should be reckoned with in the consideration of projected lines. A railway can only be run to advantage when the traffic is large enough to fill the trains quickly.

Retrenchment and reduction were carried out extensively. The staff was reduced by 1,702 men and a 5 per cent. deduction was in force on salaries.

#### Central South African Railway.

The following is a summary of the financial results of the year's working:—

Revenue	Year	
	1908.	1907.
Passengers ... ..	£1,080,588	£1,093,333
Parcels ... ..	85,364	83,381
Goods ... ..	1,883,746	1,826,060
Coal ... ..	892,929	868,536
Live Stock ... ..	113,559	82,928
Miscellaneous .. ..	93,283	185,393
	£4,149,469	£4,139,631
Expenditure	Year.	
	1908.	1907.
Working Expenditure ...	£1,938,274	£2,011,154
Contributions to renewals fund ... ..	426,733	356,281
Special expenditure charged to working ... ..	139	1,941
	£2,365,146	£2,369,376
Balance, being surplus of gross earnings over gross expenditure ... ..	1,784,323	1,770,255
	£4,149,469	£4,139,631

The diminution of oversea traffic and the increase of local traffic, which have been going on for some years, continue, and though the growth of local production is a healthy feature it has disadvantages from a railway point of view. For not only is the revenue per ton derived from the transport of local traffic less than one-fourth of that derived from through traffic, but the cost per ton per mile of working such local traffic is much heavier, because in the first place terminal services, which represent a considerable factor in railway costs, have to be performed at both ends of the journey in the case of local traffic and at one end only in the case of through traffic, and in the second place the bulk of the through traffic is conveyed for at least the whole distance of an engine run, while the bulk of the local traffic is carried for distances considerably less than an economical engine run. In most cases the trains must run for the full distance, whether traffic is available to the full haulage capacity of the engine or not. The very fact of there being traffic to be either detached or attached at intermediate stations without other traffic being available to take its place makes the working less economical than in the case of through traffic.

It is however very satisfactory to find that the figures show a remarkable agricultural development in the Transvaal and Orange River Colony, and the credit is given chiefly to the wisely directed and sympathetic interest and assistance afforded to the agricultural and pastoral industries by the Governments, the Directors of Agriculture and their officers.

---

### **Kowloon Canton Railway.**

It is believed that the heading driving in Beacon Hill Tunnel will be completed much earlier than was expected last year, but it is not anticipated that the date then fixed for the opening for traffic—May, 1910—can be altered. The cost of the tunnel driving was much reduced during 1908, but the estimate will be very largely exceeded; this is attributed principally to the unusual hardness of the rock which is quite different from that usually met with in the colony. Some of the bridges are defective, and the unevenness of the hard stratum under the foundations has been given as a reason for this, but the principles on which they were built do not appear to be satisfactory. The expenditure, the Governor remarked in his statement to the Legislative Council on the 13th May, is not an exhilarating subject. The original estimate, admittedly a very rough one and not including many important items such as rolling stock, workshops, &c., was \$5,053,274. The last estimate is \$11,004,118, but this is for a scheme widely different from that which was the subject of the original estimate. On this the

Governor stated: "I would remind you that the mere fact of inaccuracy in estimates does not mean a reflection on British engineering skill. It is due partly to the fact that we are engaged in constructing a tunnel such as has not been undertaken in this part of the world before, and the conditions of which both as regards labour and as regards explosives were extremely difficult to foresee. The variations under the estimates are also in part due to the fact that all the data of the railway were not known, and indeed are not known fully yet. Even had the railway been in the hands of contractors many items would of necessity have been excluded, for which supplementary estimates would have been required.

The South Indian Railway Co., Ltd., have agreed to lend the services of Mr. E. S. Lindsey temporarily so that he may undertake the duties of Chief Resident Engineer on the railway."

---

### Ceylon.

The construction has been approved of a broad gauge railway from Madawachchi to Talai Manaar. The former place is a station on the Northern Railway 142 miles from Colombo, and the latter is at the north-western end of Manaar Island. The railway will run generally in a north-westerly direction and will be about  $67\frac{1}{2}$  miles long. It will pass through gently undulating country on the mainland and will be carried to Manaar Island on an embankment, with openings where necessary. Screw pile piers will be provided at the northern and southern sides of that island. It is hoped that the line will secure all the passenger shipping traffic from the south of India to the east and west, as there will be a saving of time, and transshipment at Aden will be avoided. It is proposed therefore to use 80 lb. rails and lay a road which will enable comfortable rolling stock to be run at good speed. The steepest gradient will be 1 in 132 and the sharpest curve 19·10 chains in radius.

The best means of dealing with the traffic between the termini of the Indian and Ceylon Railway appears to be by steamers from Rameswaram Island to Talai Manaar, and two piers are proposed at the end of the Ceylon line, to enable steamers 250 feet long and drawing 10 feet to lie alongside. It is expected that if all the conditions are favourable the line will be completed in two years from the date when all the land is available.

The Secretary of State has approved a proposal to extend the railway which connects Colombo with Negombo in a northward direction as far as Chilaw. Instructions have been given for the preparation of detailed surveys and estimates for this line.

### Nigeria.

On 27th August, 1908, the Lagos line to Ilorin, the 247 mile point, was opened, and the occasion witnessed the meetings of the Governors of Southern and Northern Nigeria at railhead. It was hoped that rails might have been brought to Jebba by the end of the year, but this result was not achieved. Progress on the extension to Zungeru, 120 miles from Jebba, was unsatisfactory owing to the inadequate labour supply. To link up the railway systems of Southern and Northern Nigeria about 40 miles of railway to connect Zungeru with the Baro-Kano railway are required. They are being constructed by Northern Nigeria, but will be part of the Lagos Railway.

The Lagos extensions are of an improved type compared with the parent line and are being constructed at less cost.

It is contemplated to bring the railway into Lagos and to construct new wharves at Wilmot Point, and a survey has been arranged for these objects.

It was expected that the Baro-Kano line would reach Zungeru from She at the end of October, but the end of the year seems now more likely. Progress on the Northern portion of the Jebba bridge has been delayed by sickness, and completion can hardly be looked for before April.

The gross revenue of the Lagos Railway in 1908 was £146,382 and the working expenses £103,425. The net receipts were considerably less than in 1907, partly in consequence of the slackness of trade and the partial failure of the cotton crop; but a more permanent cause is that the new lines above Oshogbo cannot be remunerative for the present or for some years to come. It may fairly be expected, however, that in a little time the rails will get much of the traffic that still goes by primitive transport, especially kola nuts, and a demand may spring up for shea nuts and butter from the country north of Oshogbo.

The report states that it has not been found possible so far to replace to any appreciable extent the comparatively highly paid European artisan by less expensive coloured skilled labour. The West Indians who have been tried have not been satisfactory. A few native youths have been trained, but on the whole the natives do not appear to make much use of the opportunities offered. Doubtless the efforts in this direction will bear more fruit in time, but it is a slow process.

---

### Gold Coast.

The revenue of the Sekondi-Coomassie line in 1908 was £151,423 and the recurrent expenditure £75,124, the net revenue being equivalent to 4.15 per cent. on the capital account. The mining

inactivity has affected every feature of business, and probably the plague affected the traffic. There are signs, if market movements go for anything, that the mines are becoming more active and a better year may be looked for. The percentage of sickness among the European staff was 3·15; this clear proof of improved sanitary conditions should greatly encourage commercial enterprise.

A survey will be made with a view to the possible extension of the Accra-Akwapim line. It has been decided to extend the Accra breakwater by 250 feet.

---

### Sierra Leone.

This line has a 2 feet 6 inches gauge, and it is found that the average load the engines are capable of hauling as compared with the Gold Coast Railway is only one-fifth, a result which may be cited as an argument against this narrow gauge in similar circumstances. The railway suffered from the depression of trade in 1908, but the main line would have shown a profit of about £10,000 but for an extraordinary expenditure of £16,422 on foot bridges, new quarters and rolling stock.

---

### Uganda.

The accounts of this railway for 1908-9 show a slight increase of profit over the previous year, but the traffic seems now to have got to a stationary point for the present. The Acting Manager in his report states that: "East Africa differs from most new countries in which no sooner is a Railway constructed than a large volume of traffic flows in for export. Here, up to the present, little has been produced, and the Government has not only had to construct a Railway, but is loudly called on to provide almost everything else. Unfortunately we do not run to Rain Makers (that indigenous artist so cherished by the aborigines). The exceeding scantiness of the rainfall in this part of Equatorial Africa has for the past two years unquestionably checked progress prejudicially, and very largely accounts for the disappointment experienced. On all sides one hears the same story. Extended to Uganda this scanty rainfall has resulted in smaller loads for steamers and the curtailment of our longest lead and most profitable traffic.

"Up to the present the return from reduction in rates has about equalled economies and improvement in working. Nowhere has a reduced rate largely affected earnings, for the very good reason that most of the reductions have been inoperative through the insignificant volume of traffic offered, and beyond the benefit to the settlers and residents generally in lower rates on most of the necessaries of life, there is little appreciable gain."

In East Africa everything depends on the rainfall, and if this fails crops will not grow, food is dear, and the expected traffic does not make its appearance. Every shortage of an inch of rain means the loss of many hundreds of tons of export.

**Trinidad.**

The revenue earned in 1907-8 (£102,624) was the highest in the history of the railways, and the surplus of earnings over working expenses covers the charge for interest and sinking fund and leaves a balance of £17,320. The carriage of sugar has increased, but the principal development has been in cocoa, which was disposed of largely at high prices. The colony is to be congratulated on a remarkable recovery.

**Depreciation.**

At a conference of General Managers of British West African Railways, held at Freetown in April, the question of renewal funds was considered. The necessity for replacements is of course accentuated by the destructive character of the climate. At present "The West African Railways are living to a considerable extent on the capital value of the permanent way, rolling stock, &c., and leaving to a subsequent period the provision for renewals." The contribution suggested, based on the estimated life of each class of asset, is as follows :—

Permanent way material	...	5	percent.	perannum	on	capital	cost.
Locomotive and rolling stock	...	7½	"	"	"	"	"
Brick and stone buildings	...	2	"	"	"	"	"
Wood and iron buildings	...	10	"	"	"	"	"
Plant and Machinery	...	7½	"	"	"	"	"

On the Great Indian Peninsula Railway carriages have been introduced, built with double walls to give protection from the intense heat, wood inside and steel out and in the intervening space a sheet of asbestos material is introduced, forming air-tight "pockets" between members of the framing. An electric fan is provided in each compartment, and it is found that swivelling bracket fans are most appreciated by the public since they can adjust the fans to their liking.

**Rhodesian Railways.**

In our last number we referred to a report that the closing of the main line north of the Victoria Falls was being thought of, and we are glad to learn that this is not the case. Before construction was undertaken special precautions were taken to ascertain that the prospects of traffic were good, and although up to the present the expectations have not been fulfilled, we understand that there is no idea of closing the line. The railway was planned on a business footing, and in good time may bear out anticipations.

## MEDICAL NOTES.

TOWARDS the end of last year the Secretary of State appointed a Departmental Committee to enquire into the West African Medical Staff. Mr. H. J. Read, C.M.G., of the Colonial Office, was the Chairman, and the other members were Dr. T. Thomson, C.M.G., of the Local Government Board, Mr. W. H. Langley, C.M.G., F.R.C.S.I., Principal Medical Officer of the Gold Coast, Mr. J. K. Fowler, M.A., M.D., D.Sc., Senior Physician at the Middlesex Hospital, and late Dean of the Faculty of Medicine, London University, and Messrs. A. Fiddian and H. C. W. Verney of the Colonial Office. The Report of the Committee, together with a despatch from the Secretary of State transmitting it to the W. African Governors, has now been published as a Parliamentary paper [Cd. 4720. Price 2½d.]. Of the recommendations of the Committee the one which is likely to arouse most general interest is that for the establishment of an advisory Committee to deal with medical and sanitary questions in East as well as in West Africa. It is suggested that the Committee should be composed of two members of the Staff of the Colonial Office, one of whom should be chairman, and other members selected for their acquaintance with special branches of medical knowledge. Expert knowledge of tropical medical research, of tropical hygiene, of hygiene and sanitary administration at home, and of general medical science and practice in the United Kingdom, would in this way be represented upon it. It is also suggested that a retired Colonial Medical Officer of senior rank should be placed upon the Committee. The Committee "should be purely an advisory body, without any executive or administrative duties." They would consider such questions as schemes for

drainage and waterworks, plans for the prevention or eradication of epidemic disease, bacteriological research, &c.; and they would advise as to the selection of candidates, and the promotion of officers to fill vacancies in the senior ranks of the Service. This part of the Committee's recommendation has been accepted in its entirety by the Secretary of State. The Committee consider that the initial scale of salary of Medical Officers in West Africa (£400, rising by annual increments of £20 to £500) is adequate, but that the opportunities of promotion are hardly sufficient, and they recommend the establishment of a new grade of Medical Officers, with salary at the rate of £500, rising by annual increments of £25 to £600, to which officers should be eligible for promotion, when recommended by the Governor, conditionally on their undergoing a special course of study when on leave. This proposal has been accepted by the Secretary of State.

---

The War Office has published a Memorandum by the Director General of the Army Medical Service on the transmission of Enteric Fever by the "chronic carrier," and copies of it have been communicated to the Colonies by the Secretary of State in a circular despatch. In this Memorandum it is stated that "it may be taken as established that about 3 to 4 per cent. of convalescents from Enteric Fever become chronic carriers, and that in the neighbourhood of Enteric cases a small percentage of the community may be temporary harbourers of the bacillus." Full details are given of investigations carried out in France, in India, and at Netley and Millbank, and of the method of treatment adopted, with varying degrees of success, to eliminate the Typhoid bacillus from the "chronic carrier." It is clear that research on these lines is still very far from finality.

---

We have received three further Bulletins (Nos. 7, 8 and 9) issued by the Sleeping Sickness Bureau.

## COLONIAL STAMPS.

In our issue of January last we pointed out that the colours of the 8d., 10d., 1s. 6d., 4s. and 8s. stamps would not in all cases be found to correspond exactly with the new colour scheme, inasmuch as the colours appropriated to the Key & Duty plates are reversed. It may interest some of our readers to know how this occurred.

The scheme was originally drawn up with a view to the stamps printed from the new Universal Keyplate, like those of the Nyasaland Protectorate. When these colours came to be applied to stamps printed from the old Universal Keyplate, it was found that the larger part of the stamp would have to be printed in the singly fugitive colour. This was not desirable, and it was decided to reverse the colours.

In a recent number of "Gibbons' Stamp Weekly" a statement appeared that the Straits Settlements Government adopted a fresh design for their 1, 3, 4, and 8 cents stamps for artistic reasons. The fact was that the numbers of stamps required of these values were sufficiently great to justify the expense of special plates so as to enable these stamps to be printed more cheaply. Whenever such special plates are required, it is, of course, possible without additional expense to vary the design of the border, and to do so presents many advantages which are worthy of consideration.

ANTIGUA has received a supply of 1d. stamps in one colour.

BERMUDA has had a supply of 2½d. stamps in one colour.

CAYMAN ISLANDS are adopting a 1d. postcard and newspaper wrapper.

GAMBIA.—1d. stamps have been supplied for the first time in the red colour generally adopted by the countries of the Postal Union instead of the carmine hitherto seen in these stamps.

GIBRALTAR.—2d. and 1s. stamps have now been printed in the new colour.

GOLD COAST.—1s. stamps in the new colours have been supplied.

JAMAICA.—The last supply of stamps included 3d. and 6d. stamps in the new colours and printed from the old Queen's Head plates. The paper is, as hitherto, unsurfaced.

It has been decided in future to print all stamps over the value of 2½d. in doubly fugitive ink, and consequently on surfaced paper. This decision was not arrived at until after the printing of the 3d. and 6d. stamps, the despatch of which is chronicled above.

ST. KITTS.—6d. stamps have been supplied for the first time on surfaced and multiple watermarked paper.

**MALTA.**—New  $\frac{1}{2}$ d., 1d. and  $2\frac{1}{2}$ d. stamps have been supplied.

The penny stamp has been for some time in use with the surcharge "Revenue," but not for Postal purposes.

**MAURITIUS.**—A supply of the new 1, 5, 8, 12, 25, and 50 cents and R.1, Rs.2.50 and Rs.5 stamps, referred to in our issue of October last, has been despatched, and in addition a supply of Rs.10 stamps printed from the old Universal King's Head Keyplate in the colours appropriated to the 10s. value in the new colour scheme.

Letter cards of the value of 4 cents are also a new feature.

**MONTSERRAT.**—The following stamps in the new colours have been despatched: 2d., 3d., 6d., 1s., 2s., 2s. 6d. and 5s. The transposition of the colours referred to above will be seen in the 5s. value owing to the preponderance in area of the border over the centre.

**NATAL.**—2d. stamps will in future be printed in all grey, and no more  $1\frac{1}{2}$ d. stamps will be supplied.

**ST. VINCENT.**—With reference to the note in our last issue with regard to the colour of the 2d. stamps it of course followed that the 3d. stamp when required will be printed in the colour allocated to that value in the new colour scheme, which is not sufficiently dissimilar to that in which the 2d. stamp is at present printed. A supply of the 3d. stamps has now been made; also of 1d. and 6d. stamps with the stops under the "d" of 1d. and 6d.

**STRAITS SETTLEMENTS.**—30 cents stamps, as described in our April issue, and \$2 stamps in the colours appropriated to 5s. and \$100 in those appropriated to the 3d. value, but with the name of the Colony and value in green, have been despatched.

**TRANSVAAL.**—2d. stamps in all purple will shortly be despatched. 6d. stamps on ordinary and £1 on specially surfaced paper have been supplied. In the two latter cases the existing colours have been retained.

**TRINIDAD.**—A supply of the new 1d. stamps referred to in our April number has been despatched.

**TURKS AND CAICOS ISLANDS.**—The complete series of new copper-plate stamps have been supplied, as described in our last issue. The values are the same as hitherto.

**THE GOVERNMENT OF BRITISH HONDURAS** has instructed the Crown Agents for the Colonies to announce that the whole remaining stock of Queen's Head stamps is for sale in this country. The stock includes a number of 25 cents stamps surcharged "Revenue." These stamps were not used solely for revenue purposes but were, and are still, available for prepayment of postal charges. The whole series of stamps was in exclusive use for a few months ending September, 1907, owing to the stock of King's Head stamps received in December, 1906, being found to be defective.

Particulars of the stamps may be obtained on application at the Crown Agents' office in Whitehall Gardens.

## The Colonial Service.

10, PARK TERRACE, OXFORD,

5th August, 1909.

THE EDITORS OF "THE COLONIAL OFFICE JOURNAL."

DEAR SIRS,

Will you allow me a word of reply to the interesting and courteous criticism in your July number of my lecture in Brussels on British colonisation in the Tropics?

You say that I am "somewhat unduly pessimistic." As Belgium possesses a Home Civil Service inferior only to our own, it seemed unnecessary to dwell with emphasis on some of our more obvious merits; on the other hand, she is now endeavouring to call into existence a colonial service, and that, too, in a region where neither the existing system nor its administration are satisfactory. In these circumstances it seemed to me most likely to profit my audience if I pointed out in some detail the errors which we had made and were making. Viewed as a complete statement of the present position and tendencies of our colonial administration, my lecture was therefore incomplete.

In reply to my charge that an insufficient number of officials at the Colonial Office have first hand information regarding the Colonies, your answer is in effect that I underrate the number who have such knowledge, and that such knowledge is a highly dangerous thing for them to possess. "The knowledge acquired soon gets out of date, and it would obviously be unsafe to rely much on it. Any attempt by the civil servants at home to judge colonial questions upon facts which they have themselves collected is sure to be dangerous." Here I think that you underrate the intelligence of your colleagues. They are not half-educated M.P.'s or globe-trotting journalists, but the pick of our English Universities, and can be trusted to use even a little knowledge in the proper way. Both the Office in Downing Street and the Crown Agents' Department are constantly required to decide questions of administration or of the purchase of supplies; at present they are frequently compelled either to confine themselves to minuting and tying up in pink tape the proposals of the man on the spot, or to decide without local knowledge between the claims of rival experts. Some of the worst mistakes of the Office in the past have been due to inability to see that the local officer was not an expert but a faddist, others to inability to see that he was not a faddist but an expert. You say that "the essential question is not how much

the handful of men in the Colonial Office have seen of the colonies, but how the local work is done by the men who are sent out to do it." I agree; but surely the best way of finding out how it is done is by going to see. "The Colonial Office criticises, controls, and assists administration;" I refuse to believe that men of the intelligence and training of the Colonial Office Staff would not criticise, control, and assist the administration of East Africa or Northern Nigeria more efficiently if to their intelligence and training were added local knowledge, and the sympathy which local knowledge gives.

I am glad that you agree with me that in the training of our colonial service there is room for improvement. The average man whom I have met goes out with the feeling that if he treats the natives in a sporting spirit of English fair play, all will be well. To me it seems highly desirable that he should add to this at least the knowledge that the tribes with whom he is to deal have highly complicated legal and social systems, based on ideas of justice differing widely from our own. To train candidates in all the minutæ of native law, custom, religion and language, is, of course, neither desirable nor possible; but to raise the present three-month course to at least six and to add to it definite anthropological instruction would do much to make the first steps of the young administrator more sure and wise. At the end of this lengthened course there should be a much more stringent examination than at present. I do not think that we should imitate the method of the Indian service and choose our candidates by examination. Better results are in my judgment attained by the present method of selection; but when candidates have been selected, their course of training should be made a reality by a stringent examination at its close.

Our differences are rather of emphasis than of principle; it is therefore unnecessary for me to worry you with a longer letter.

I am, yours etc.,

W. L. GRANT.

## RECENT TRANSFERS AND PROMOTIONS MADE BY THE SECRETARY OF STATE.

- Captain J. QUAYLE DICKSON, D.S.O. (late Native Adviser, Orange River Colony), Deputy Commissioner and Resident, Gilbert and Ellice Islands.
- Dr. T. A. DOWSE (Government Medical Officer, Fiji), District Commissioner and Government Medical Officer, Caicos Islands.
- Mr. W. A. BOWRING (Local Auditor, Uganda), Island Treasurer, Cyprus.
- Mr. G. A. NEVILL (retrenched from South African Constabulary), District Resident, Third Class, Nyasaland.
- Mr. H. P. HART (retrenched from South African Constabulary), District Superintendent of Police, Uganda.
- Mr. G. W. LYALL (retrenched from the Transvaal Civil Service), Chief Clerk in Secretariat, Uganda.
- Mr. G. W. KNAPMAN (retrenched from the Transvaal Civil Service), Head Clerk in Land Office, East Africa Protectorate.
- Mr. R. HART (Postmaster, Nyasaland), First Class Postmaster, East Africa Protectorate.
- Dr. R. A. CLEVELAND (District Medical Officer, Cyprus), Chief Medical Officer, Cyprus.
- Mr. A. EARNSHAW (Stipendiary Magistrate, British Guiana), Puisne Judge, Gold Coast.
- Mr. A. F. C. WEBER (Stipendiary Magistrate, British Guiana), Puisne Judge, Southern Nigeria.
- Mr. J. F. CARGILL (Resident Magistrate, Jamaica), Puisne Judge Jamaica.

- Mr. E. St. J. BRANCH** (Colonial Secretary and Attorney-General, Leeward Islands), Attorney-General, Jamaica.
- Mr. H. E. W. GRANT** (Colonial Secretary, Falkland Islands), Colonial Secretary, Leeward Islands.
- Mr. J. BROMHEAD MATTHEWS** (Attorney-General, Bahamas), Attorney-General, Straits Settlements.
- Mr. W. S. WRIGHT** (Assistant District Commissioner, Uganda), Registrar of the High Court, East Africa Protectorate.
- Mr. N. C. RUGGLES** (late Assistant Resident Magistrate, Transvaal), District Magistrate, Dominica.
- Mr. A. L. CASTELLAIN** (retrenched from South African Constabulary), District Commissioner, Northern Territories, Gold Coast.
- Captain W. SWIRE** (Company Commander, Somaliland Standing Militia), District Commissioner, Northern Territories, Gold Coast.
- Mr. C. W. WELMAN** (late of Education Department, Transvaal), Assistant District Commissioner, Gold Coast.
- Colonel C. A. FRANCIS** (Commandant of Armed Constabulary, Fiji), Stipendiary Magistrate, British Guiana.

## OFFICIALS ON LEAVE OF ABSENCE IN THIS COUNTRY WITH DATE OF EXPIRATION OF LEAVE.

—

This List is compiled from the Leave Certificates sent to the Crown Agents for the Colonies. The Editors will be glad to receive notice of any other cases of Colonial Officials on Long Leave.

—

## EDITORIAL NOTES.

AUSTRALIAN State Ministries are often exceedingly short-lived, but the experience of Mr. Earle's Labour Ministry in Tasmania, which suffered defeat on its very first appearance before Parliament, has been more than usually unfortunate. We are not concerned with the issues which led to this disaster; but we may be allowed to express our regret at the occurrence from the point of view of those who take an interest in political experiments. For the composition of Mr. Earle's Cabinet was determined not in the ordinary way, by the selection by the Premier of those whom he desired as colleagues, but by a direct vote of the party caucus. The expedient of elective Ministries has long been advocated by the upholders of extreme democracy in Australia; but, unless we are mistaken, it has usually been proposed that they should be elected not by a single party, but by Parliament as a whole. In this shape the proposal was very adversely criticized by Mr. Bernhard Wise in a work which we recently reviewed, and he stated that it had received no support from any ex-Minister who had practical experience of the difficulties of party politics. This statement is, we think, somewhat too sweeping, as we believe that Sir John Cockburn may be numbered among its advocates. But the idea has never yet been put to the test of

practical experience. Some of its supporters no doubt see in it a means of breaking down the party system altogether, and substituting composite "ministries of all the talents" for the existing party cabinets. It may be questioned whether this result would be achieved, and it seems clear that the change would encourage individual politicians to set personal ambition before co-operation and play for their own hands. But whatever might be the effect of the election of ministers by Parliament, their election by a party meeting would clearly do nothing to break down the sharpness of party distinctions. We are inclined to think that the advocates of this method underrate the importance of the personal considerations which affect the composition of a Cabinet. It cannot be assumed that the six or twelve or twenty most popular men in a party will work satisfactorily together in the delicate business of Parliamentary Government, and the knowledge that they owe their places to a popular vote is not likely to conduce to their sense of discipline and of responsibility to their leader. But Australian Labour parties have always kept a very tight hand on their leaders, and a Labour Premier, whether in the Commonwealth or in one of the States, can never hope to enjoy the same degree of freedom and power as a Premier under existing conditions at home.

---

The Commonwealth Parliament has had before it a Bill for the surrender to the Commonwealth Government by the Government of South Australia of the so-called "Northern Territory" of the latter State. The Bill provides for the ratification of an agreement concluded in December, 1907, between Mr. Deakin and Mr. Price, and since ratified, in so far as South Australia is concerned, by an Act passed by the Parliament of that State. Under the terms of the agreement the Commonwealth is to take over the whole of the Territory and the State property situated in it, including the Palmerston and Pine Creek Railway, which runs southwards from Port Darwin; and is also to acquire the Port Augusta Railway, running from the harbour of that name on the southern coast of the State northwards to Oodnadatta. The Commonwealth would thus become the owner of the two terminal stretches of the projected Trans-Continental Railway; and it is a condition of the agreement that the Commonwealth should complete the line by bringing the two terminals into connection. The Commonwealth is to take over the loan liabilities incurred by South Australia on account of its Northern Territory, amounting in all, including advances, to some £3,330,000. The State is to facilitate the construction by the Commonwealth Government of a line running westward, from some point on the Trans-

Continental Railway, to connect with the Western Australian system. It will thus be seen that, if the policy embodied in the agreement is carried into effect, Australia will at last be provided with a complete network of interconnecting railways, though, unfortunately, the difficulties arising from the use of different gauges will continue.

---

In connection with the important question of this proposed transfer the Commonwealth Department of External Affairs has prepared a very interesting Memorandum on the Northern Territory. This Territory formed part of the Colony of New South Wales until July 6th, 1863, when by Letters Patent it was annexed to South Australia. Its surrender to the Commonwealth is made possible under the terms of Section 111 of the Commonwealth Constitution. At the present moment the Territory is sparsely populated and little developed. Even the preliminary task of exploration is by no means complete, and its value to the Commonwealth lies only in the hope of future potentialities. Attempts at settlement date back as far as 1824, but we are told that "the population returns show that the country is still practically uninhabited," that "the mining industry at present is at a low ebb, and unable to employ more than comparatively few persons," and that "agriculture to-day is practically non-existent." A South Australian Royal Commission enumerated in 1895 a variety of causes for the failure to develop the country, but it proved easier to enumerate the causes than to remove them, and it is not surprising that South Australia should have shown a readiness to relinquish the Territory, provided that satisfactory terms could be arranged, almost immediately after the establishment of the Commonwealth. In the absence of a connecting railway, Adelaide was obviously not a convenient centre from which to control it.

---

Writing to the Federal Government in April, 1901, the late Sir Frederick Holder—the news of whose recent death has been received with widespread regret—drew attention to one very important aspect of the question of the Northern Territory. "I may mention," he said, "that had South Australia been willing to have given *carte blanche* to capitalists to introduce coloured labour into the Territory, a sum of money, estimated at about £10,000,000, would have been forthcoming to establish a chartered company to take over the Territory, with its assets and liabilities to South Australia, and to carry out the construction of the remaining portion of the overland railway. This offer was

declined by the South Australian Government in its own interest and in the interests of Australia." Exploitation of the resources of the Northern Territory, so far as it has proceeded at all, is, we believe, largely in Oriental hands, but the figures given in the Memorandum show that there has been no considerable influx of Oriental population. The number of aboriginal natives in the Territory is estimated at from 20,000 to 25,000, but may be considerably larger. The Europeans in 1908 numbered 1,081, and "others" 1,892. It is no doubt felt in South Australia that if the maintenance of the "White Australia policy" entails, in respect of the Northern Territory, serious economic sacrifices, those sacrifices ought to be borne, or at least shared, by the Commonwealth as a whole.

---

There can be little doubt that the possibilities of the Northern Territory are considerable. On the coast there is a heavy rainfall, and the country is more fortunate in the possession of navigable rivers than any other part of the continent. The soil is well suited to a variety of tropical products, and the hopes of important mineral discoveries appear to be well founded, but until exploration has been very much more general and systematic, no certain opinion can be expressed. Quite recently there is said to have been an important gold discovery in the south-west corner of the Territory, which might perhaps somewhat change the disposition of South Australia to surrender the Territory. But for many years to come it can hardly fail to be a source of expense to the government which administers it, and the shoulders of the Commonwealth are broader than those of the State, especially now that the revenues handed over to the latter are to be curtailed.

---

Mr. Frank Tate, the Director of Education in Victoria, has recently made an official tour in Europe and America, and has written a preliminary report which is of great interest. He has been impressed by the deficiencies of Victoria in the matter of the provision by the State of education other than elementary; and he comments on the similar deficiency until very recent years of the English educational system. But he sees much to admire in the progress now being made in the work of making good this deficiency, and the expectation, based on advice given to him at home, that he would find that Victoria had little to learn from England, was happily disappointed. It is useful to have an estimate of recent educational progress in England made by an acute and impartial observer who is not concerned with party politics, and we therefore reproduce the passage in Mr. Tate's preliminary

chapter in which the matter is discussed:—"The last of the great nations to face the problem of national education from the elementary to the highest grade is Great Britain. Long before the Education Act of 1870 her more enlightened neighbours had made very full provision for popular education, but the English Act of 1870 (which we unfortunately followed slavishly) established elementary education only. For the modern conception of national education was slow to take root in England. Her elementary schools were not established, as in America, from any belief that all the children of the State have a right to demand a fair opportunity for full mental development, nor did she take the European view that national efficiency rests upon school efficiency. Robert Lowe put the case aptly when, after the passing of the Reform Act of 1867, he said, 'We must now, at least, educate our new masters.' On the whole, popular education in England was undertaken grudgingly and distrustfully. It was unlikely, therefore, that a people who took up the business of public education in this spirit would make much of a success of it, and so it proved for the next thirty years. The idea, that popular education by the State partakes of the nature of charity, persisted long in England, and does so in Victoria to some extent. It is hard to credit that the most elaborate regulations were issued for defining the various classes of people who might rightly use State-aided schools. The schools prior to 1870 were for 'the labouring class only.' In the Regulations of the English Education Department, 1864, we find: 'Simple policemen, coastguards, and dock and railway porters may commonly be regarded as labouring men. But petty officers in those services, excise-men, pilots, and clerks of various kinds, present more difficulty, and must be judged of according to the answers to the preceding inquiries, *e.g.*, Does he rank and associate with the working men or with the tradesmen of the place?' When in Switzerland, I quoted the above regulation to a Swiss gentleman, who smiled, shrugged his shoulders, and said expressively, 'Ah, yes, that explains so much in English education.'

"There have been many attempts in England since 1870 to build up technical and intermediate education, but no comprehensive system was agreed upon until a few years ago. The Act of 1902 inaugurated a new era in public intermediate and secondary education, and since then the greatest energy has been put forth in establishing efficient secondary and intermediate schools at public expense, and the old-time prejudices have vanished, or are vanishing fast. The mother country has been slow to move, but now the movement is going forward with characteristic determination. Before I left Victoria, I was advised by many that I

should find little of interest or value in English popular education. On the contrary, I found the conditions in England intensely interesting, and of the greatest value to me, seeing that the beginnings of our own system were modelled on those of England. The pity is that while we adopted the restricted English views of 1870, we have not followed the advances made since. When, in 1895, the School Boards of England were developing higher elementary schools, we were too much occupied with the drastic retrenchment which called forth the scathing condemnation of a Royal Commission in 1899, a retrenchment whose damaging effects the Education Department is still feeling.

“ During the past six years the attitude towards public education in England has completely changed. Instead of public moneys spent on education being more or less restricted to elementary education, it is now competent for county and borough councils ‘ to consider the educational needs of their area, and to take such steps as seem to them desirable, after consultation with the Board of Education, to supply or aid the supply of education, other than elementary, and to promote the general co-ordination of all forms of education.’ England has at last begun to work out a national system of education, and to follow in the footsteps of other progressive peoples.”

Missions similar to Mr. Tate's have recently been undertaken by the Directors of Education in South Australia and New Zealand, and it is to be hoped that they will lead to a healthy competition in educational matters, on the part of the dominions with Europe and with the United States of America.

---

The action of the House of Lords with regard to the Budget has caused many references to the Victorian crisis of 1879. That case, however, is not of much value as a precedent, for in the Constitution Act of 1854 it was specifically enacted that the Legislative Council should not have power to alter a money bill. On this occasion it was alleged that the bill contained other than money provisions, by “ tacking ”; but in a contemporaneous case in Tasmania the Council returned appropriation bills cut down to supplies for the first six months of the year, on the ground of excessive expenditure by the Government. Eventually the difficulty was got over by a coalition government. Throughout these controversies the Secretary of State upheld the right of the Assembly of “ limiting the matter, manner, measure and time of grants of supplies to the Crown.”

A problem of the future will be how to utilise the desert spaces of the earth, and in Australia, which possesses some million square miles of land under a 10-inch rainfall, any production which may be found practicable in such regions will be an enormous gain. There is a prospect that the prickly pear, hitherto regarded as a nuisance to be cleared off as well as possible, may be cultivated in such a way as to become a valuable product. The plant if the spines are off yields an excellent cattle food, a fair amount of alcohol, a large quantity of glucose, and a fibre which might be suitable for making paper. In America a thornless or spineless plant has been produced and developed by cross-breeding, and it is claimed that it will stand arid conditions as well as the spiny varieties, and produce ten tons of feed where the wild sort only produces one.

---

The Transvaal has now followed the example of Canada by passing an Industrial Disputes Act, the provisions of which are closely modelled upon those of the "Lemieux Act," of which we have given an account in previous numbers. Mr. Jacob de Villiers has publicly acknowledged his indebtedness to the Canadian model. The Transvaal Act applies to the mining industry, to undertakings carried on by local authorities for the supply of gas, electric light, water or power, or for tramway or sanitary purposes, and to any other industries which the Governor may proclaim. Only white employees come within the scope of the provisions of the Act. The Act further provides for the establishment of a Department of Labour and for the appointment of an Inspector of White Labour.

---

Last year the Natal Government introduced a Bill providing for the cessation, at the end of three years, of Indian immigration into the Colony. This measure never became law, and an undertaking was given that a Commission should be appointed to enquire into the whole question. The report of this Commission has now been issued, and it affords interesting reading. It states with the utmost frankness that "the Indian is undesirable in this Colony other than as a labourer," but his presence in this capacity it regards as essential to the prosperity of the Colony. The Commissioners express the opinion that, allowing for the number of natives leaving the Colony for employment outside its borders, and for the fact that the native's average period of labour is not more than six or eight months, "practically the whole of the native labour supply is in employment during the course of the year." They believe that the native is able to find all the

employment he desires, and that the expansion of industries resulting from the presence of the Indian has provided the native with further openings for employment. They find that a number of industries (including sugar, tea and wattle growing, farming and coal mining) are dependent on the Indian labour supply, and must decline, or even be abandoned, were it withdrawn, and they regard it as essential that an alternative source of supply should be guaranteed before Indian immigration is discontinued.

---

The policy of Natal has always been to keep the Indian solely as a labourer. But the original immigration system did not conduce to this end. The immigrants could become "free" after five years' indentured service, while they were not entitled to a return passage to India for ten years. The expectation that they would either voluntarily re-indenture or become available as free labourers was not fulfilled, the majority electing to employ themselves in farming, market gardening, and kindred pursuits. In 1897 an Act was passed imposing an annual licence fee of £3 on Indians who did not renew their indentures or return to India, but it appears to have been laxly administered until 1903. Since then it has been enforced more strictly, and appears to be effecting its object. Of 7,735 Indians whose indentures expired in 1908, 3,989 returned to India and 3,304 entered into fresh indentures, while 1,233 "free Indians" whose indentures had expired prior to the Act of 1897 re-indentured, thus becoming subject to the provisions of the Act, and the Commission "feels assured that a continuance of this state of affairs will gradually cause the cessation of the settlement of time-expired Indians in the country." The report is no doubt representative of prevailing opinion in Natal, and sufficiently explains the decision of the Natal Government not to proceed with the bill for terminating the immigration of Indians. What policy the Union Government and the Government of India may ultimately decide to adopt is another matter.

---

The Committee which the Secretary of State appointed to conduct an inquiry into the Liquor Trade in Southern Nigeria has recently presented its Report, which has been laid before Parliament. [Cd. 4906. Price 2½d.] The document has excited great interest, and, in many quarters, a good deal of surprise. The committee summarize their conclusions in the following terms:—"There is absolutely no evidence of race deterioration due to drink. In Southern Nigeria mortality is high and disease is rife, but drink is only an insignificant factor in producing these results. There is hardly any alcoholic disease amongst the native

population, and with the exception of one or two isolated cases we found no connexion between drink and crime. On the occasions of feasts and festivals the natives often drink more than is good for them, both of trade spirits and native liquors. Individuals injure themselves both morally and physically by indulgence in drink, but the people generally are a sober people, who are able to drink in moderation without falling into excess. There appears, however, to be a tendency among some of the natives who have received a certain amount of European education to acquire drinking habits, but the prohibition of the import of 'trade spirits' would not do much to diminish this evil. As education progresses this tendency will doubtless be carefully watched. The expert evidence taken in England shows that there is nothing to complain of as regards the quality of the spirits imported into Nigeria."

---

It will be apparent from the above that any expectations that the Report would embody "horrible revelations" as to the prevalence of drunkenness in Southern Nigeria, and the exploitation of the vice among the natives for the benefit of European traders, have been disappointed. The Committee are evidently of opinion that wholesale charges of this character cannot be substantiated, and in a number of cases in which specific allegations were made, their investigation of the evidence has led them to the conclusion that those allegations were ill-founded. This is particularly the case with regard to a statement that at a particular school an enormous proportion of the children—60 out of 75—ranging in age from eight years to sixteen, were "regular gin-drinkers." It is satisfactory to find that this charge is completely disproved. It appears to have been based on ignorance of the native language and imperfect interpretation—a fruitful source of mistake in dealing with native populations all the world over.

---

The most piquant passage in the Report is one in which comparisons are instituted between the United Kingdom and Southern Nigeria. "It goes without saying that the standard of sobriety in Southern Nigeria is very much higher than that of the United Kingdom. Speaking of Abeokuta, a town of 150,000 people, one missionary, who was a strong advocate of temperance, volunteered the statement that you could see more drunken men in the Wandsworth Road in one night than you could in three years in Abeokuta. Another witness said that he had seen more drunkenness in one day in Bristol than he had seen in the whole of his experience of 13 years in Southern Nigeria. Dr. Currie, in reply

to questions asking him to compare Ibadan with places in England of which he had experience, replied that the two could not be compared:—‘You cannot compare Barnsley with Ibadan,’ he said, ‘because one is a drunken town and the other is not.’ And then asked with regard to the district round St. Bartholomew’s Hospital, he said again:—‘You cannot compare the two. Smithfield is a dirty, drunken district and Ibadan is not.’ Dr. Manners, speaking of Brass and Bonny and asked to compare them with the districts round St. Thomas’s Hospital, replied:—‘Lambeth would not compare well. I do not take Saturday nights because that would be unfair, but an ordinary night in Lambeth would not compare favourably with any village in the Brass district.’” We have been expecting a protest from some of the localities here singled out for censure. Perhaps the circumstance which seemed to make the case of Southern Nigeria suspicious was that nearly 50 per cent. of the entire revenue is derived from the taxation of spirits, but account should be taken of the fact that the tax is, relatively to the value, enormous. We are not sure, on the other hand, that there is much in the contention that bottles of gin are used as current coin. The bottles are sure before long to work out their proper destiny.

---

It is gratifying to find that Lancashire buyers consider that the quality of West Indian cotton is admirable and the packing well done. The British Cotton Growing Association has done valuable work in establishing sound relations between the producers and the buyers. No pains are being spared to keep up the quality. At the September meeting of the Association, Dr. F. Watts stated that some of the best work has been effected in co-operation with the planters themselves. Planters are encouraged to work on new lines to improve the quality of their cotton, more especially with regard to seed selection, and whilst a good deal of work is being done on the experiment stations, more extensive experiments are carried out in the fields in co-operation with the planters. The work of seed selection is being carried on at the experiment stations in every island where cotton is produced, in order to ascertain the most suitable varieties, both as to yield and quality, and in order to secure new and improved varieties. Dr. Watts is of opinion that it is advisable to select seed from the same district in which it is planted, this being, in his opinion, the method best calculated to improve the quality, and to produce a race of cotton capable of withstanding the pests and diseases incidental to the district. If seed is taken from a district where there are no pests or diseases, and planted in another part, it is

possible that the strain may be overwhelmed by pests there existing which the plants have not been trained to resist, whereas by selecting hardy varieties, which have become acclimatised in the district, it is possible to produce varieties which will be able to withstand the ravages of the pests, and for this purpose it is desirable to establish a good strain in every island, and to work it up to the highest pitch of perfection. At each experiment station, the Department of Agriculture is doing highly scientific work in efforts to raise new varieties, by utilising the best knowledge obtainable relating to plant life. These varieties afterwards are planted in the fields, when the work is taken up by the planters, in co-operation with the experiment station workers. Dr. Watts spoke in very high terms of the manner in which the Department is assisted in experiments by the planters, who take a considerable amount of interest in the subject; in this way it is hoped to maintain the character of the cotton now being produced, and also to keep the industry on a very high level.

---

The visit of Herr Dernburg to Liverpool was marked by an excellent speech, in which he made it clear that the German colonies are doing very well. Their revenue is now about £1,500,000, and there are no grants except one to German New Guinea of £40,000. If, however, the cost of local defence is reckoned in, as it should be, the total surplus, which is put at £500,000, is wiped out and turned into a deficit of £300,000. The total trade is about £7,500,000.

---

The Imperial Chambers of Commerce Congress, held at Sydney in September, unanimously recommended the completion of the Imperial cable route between Great Britain and Australia by a State-owned telegraph across Canada. The Congress undoubtedly got hold of a strong point. The Pacific cable is dependent on the Atlantic and the trans-Canadian systems. The Atlantic service might possibly be cheapened, but at any rate it is efficient. The Canadian service is sufficiently cheap but it is not efficient; errors and delays frequently occur, and the result is that the Pacific cable suffers a loss of business. It seems impossible to rectify the matter unless the Pacific Cable Board themselves take over the transmission of messages across Canada. The perfect plan would no doubt be the construction of a State-owned line across the Dominion, but the Pacific traffic alone would hardly support an entirely independent service. The solution may be found in some arrangement under which the C.P.R. would give the Board facilities for handling its messages itself over their system.

It is always interesting to see ourselves described as others see us, and the following extract may be quoted with this view from a recent work (published in America) by Mr. A. R. Colquhoun, which discusses the recently-acquired tropical possessions of the United States and compares British with American officials. "The careers of a majority of these men will not be brilliant, and the prospects held out do not, on the surface, seem likely to attract clever and ambitious youths. Entrance into the Indian or Colonial civil service means exile from home, separation from family, a salary adequate but by no means princely, with slow, if sure, increase. His highest hopes cannot soar beyond a colonial governorship. When at the zenith of his career he will receive a salary which, although handsome, will have to bear heavy demands in the way of entertainment, and provides no margin. If he marries, his early years will be a struggle to make both ends meet, and his later ones will involve frequent separation from wife and children and a constant effort to maintain two establishments in a manner suitable to his position. Though hard work will be required of him, if he is to pass successfully through the stages of advancement it will not necessarily accelerate his progress or bring a certain reward, for influence and luck play a considerable part in the matter. It must be explained that the influence will be of a social or family origin, and seldom, if ever, political in its character. Even in the appointment of colonial governors and viceroys, which are made by the government that happens to be in power, there is usually an absence of party motives, and although sometimes regarded in the light of rewards for brilliant services, the party question has little to do with them. As far as pecuniary advantages are concerned, it is well known that only men with large private fortunes can afford to accept many of the highest positions.

"The colonial career, therefore, seems to offer little attraction to a young American, who is not driven by force of circumstances to seek his fortune abroad, and who is brought up in the belief that to 'get on' is the first duty of man, and his chief pleasure.

"The attractions, from the British point of view, are, first, the social status which undoubtedly attaches to government service. This, unfortunately, is far from being the case in the United States, where a government career neither confers nor confirms a man's social standing—rather the reverse. Nor would such an inducement be a strong one to the best type of American, as it is to the best type of Englishman. Secondly, the element of adventure and the prospect of a wider field of interest in an unknown land have a strong attraction for the dweller in small,

overcrowded Britain, and the spirit of his forefathers stirs in many a youth the desire for fresh fields and a wider life, though after-experience too often proves that he merely exchanges the narrow circle at home for a still narrower one abroad. The spirit of adventure might prove as strong an inducement to the American as to the Englishman but for the fact that he does not need to leave his own country in order to gratify it; indeed, in leaving the United States he turns his back on many opportunities and also on a life of risk and excitement, of hard work and quick profits, which appeal peculiarly to his energetic nervous temperament. The third and most serious consideration to the Englishman is the pension which invariably attaches to government service, and this inducement has proved strong enough in many cases to weigh against more tempting offers of immediate advancement. Rather than forfeit this small but sure provision for old age, men have been known to refuse good and even brilliant offers. The pension will never, of course, be large enough to support a man and his family in affluence, but if he serves long enough it will make a decent and comfortable provision for his declining years, and, in case of ill-health or break-down, he will be secured from actual want. The Englishman as a rule looks forward with pleasant anticipations to the time when he can retire to a country-house, and, with the surety of a small but regular income for the rest of his life, can indulge in one of his many hobbies, take a leading part in local politics, and see his sons launched on careers similar to his own in their moderate expectations and honorable position.

“Such a provision for old age does not at all appeal to an average young American, who could not contemplate complacently an old age spent in calm retirement on a reduced income. American men do not think of old age in the same way as their English cousins; and if they do, it is merely a spur to them to make a ‘big pile’ as quickly as possible. Death is provided for even more universally than with us by heavy insurances, but no one who has any experience of the United States can fail to have been struck not only by the youthfulness of most men in responsible positions, but by the general assumption that youth and middle age are the only periods of life worth consideration.

“The British Government pursues a wise policy in granting liberal furloughs to all officials, and this must be taken not only as a compensation and inducement, but as a means of rendering the man more efficient. Without the long and regular respite from arduous duties and the renewal of the springs of life afforded by his visits home, the colonial official could hardly keep up, physically, mentally, or morally, to the standard required. The idea of giving long furloughs, on handsome pay, is somewhat

opposed to American theories. The rule is 'no work, no pay,' and the liberality of the United States Government does not apply in the matter of official salaries, which are invariably, and even scandalously, inadequate.

"The next feature in the life of colonial officialdom which makes it popular with Englishmen is that the work itself is congenial to them. Their whole training has made them self-reliant in the sense that they are prepared to take responsibilities and to act independently. They inherit a sense of justice, scrupulous fairness, and esprit de corps which are fostered by public-school training, despite its defects. They are not cowed or depressed by solitude if called upon to dwell far from any of their kind. Boys fresh from school or college go cheerfully to distant frontier districts where, excepting one or two other officials, they may not see a white man for months. After this period of training they often go to a more complete isolation. Such conditions would drive a Frenchman crazy; but, though there are occasional cases of break-down, some stolid Britons even grow to enjoy their isolation, helped by the natural taciturnity and self-reliance of their race and class.

"There is still, even in these days of luxury, a certain element of Spartan discipline in the lives of British boys which makes it far easier for them in after-life to enjoy such careers as these. The little chap who, at eight or nine, leaves his mother's arms for a boarding-school, has to cultivate at that tender age a self-possession, reticence, and decision which become second nature to him and lay the foundations of successful administration in later life. Not only does the rough-and-tumble of his school-days make the boy hard and self-reliant, and develop in him that knowledge of his own powers which will be so valuable to him, but he has, naturally, a capacity and love for ruling. He has no illusions as to the equality of the people he rules; on the contrary, he is firmly imbued with the idea of the superiority of the British race over any other, white or black. At the same time he has no repugnance or dislike for 'niggers,' regarding them generally with a sort of paternal tolerance. He enjoys the struggle with prejudice and ignorance, and likes to evolve order out of chaos, feeling himself the pivot on which the whole system turns.

"It must be remembered that the Indian or Colonial officer is almost invariably of gentle birth, and invariably of gentle education—in the best sense of the word a gentleman. This implies, in Great Britain, that he is acquainted with the ordinary etiquette of civilised society, that he has been taught the self-control and consideration for others on which that society has its basis, and

that he is not uncouth or rough in speech, appearance, or manner. When we remember that he will probably be sent as an interloper into the midst of communities civilised and cultivated in varying degrees, on lines quite different to our own, it is easy to see the value of such an equipment. The Oriental is peculiarly keen to notice any lack of breeding in the European he meets, and, contrary to the general belief, he can appreciate perfectly the difference between men who have and men who have not this quality. It is not necessary to adopt Oriental etiquette, with its endless ramifications; but the Indian, Chinese, or Malay is quick to notice if his European friend is deviating from what he soon learns to recognise as the European standard of good manners. There is an unwritten code of manners which well-bred men all over the world practise and by which they recognise each other."

## THE ADVANCE OF RHODESIA.

PROGRESS nowadays is mostly measured by dividends, and if these are forthcoming with celerity the reputation of a new country is assured. It must be admitted that the general view in this country of our undeveloped possessions is frankly material. Mining resources command the first attention, partly because in that way money is made, if made at all, quickly, and partly because the industry readily lends itself to the flotation of companies and the luxury of a gamble. Agriculture, *pede claudo*, comes second, and receives little notice unless it produces something, such as rubber, the paying powers of which can be appreciatively discussed in the financial papers. This attitude is, of course, perfectly sound, and it is comforting to find that this country, bled though it be by the foreigner and super-taxed by the Chancellor of the Exchequer, can somehow or other produce savings year by year which are sent out in ever-increasing volume to exploit and develop the overseas territories. The money invested in this way repays this country in the form of an immense variety of products which serve either as materials for industries or as food for workers, and may therefore be regarded as part of the working capital of our manufacturers and suppliers. In many cases the development of a territory overseas is the direct and obvious result of a growing want here, and this close business connection is reflected in the attention which is constantly given to colonial industries by the financial and technical papers of this country.

It is perhaps inevitable that the personal qualities of a colonial community should be a matter of secondary consideration. The British public is proud to think that an Englishman in many

places controls a great territory and population by something which is known vaguely as moral force, and more materially as the toe of his boot. But more important than these feats of administration is the effect of colonial life on Englishmen themselves, and the character which is developed by the effort to do great things in the face of difficulties, and to carve a British settlement out of the wilderness. From this point of view the story of Rhodesia is peculiarly interesting. It is the story of a handful of men who made a home in a savage country, and who will in all probability grow eventually into a great population, British in origin and character, in the very heart of the dark continent.

The history of the community of Southern Rhodesia has been one of great expectations followed by hard times. The country has a wonderful attractiveness. The first travellers must have felt an uplifting of heart when, after passing through the gaunt desolation of the Karroo and the meagre veldt of Bechuanaland, they came at last to the rich pastures and abounding soil of Matabeleland. The beauty and promise of the country increases as Mashonaland is reached. Here picturesque rivers are passed; "the scene is full of variety; dense forests of trees are succeeded by extensive grass lands, and on all sides there are signs of great fertility of soil and richness of vegetation. Everything pleases—the greenness of the veldt, the freshness and buoyancy of the air, and the varied beauty of hill and valley." Beyond Salisbury the scenery is wonderfully majestic, and the richness of the land is testified by grass growing sometimes twelve feet high. Through this part Cecil Rhodes journeyed by ox-wagon, and it is easy to imagine how deeply he was stirred by it, "taking in and devouring its wonders, seeing visions and dreaming dreams, dreams of a population which should fill this vast territory, and visions of a day when over the country there should be dotted thousands of prosperous farmsteads, inhabited by people drawn from the over crowded cities of England."

The first foothold in the territory was obtained when, in 1888, Mr. Maguire, commissioned by Mr. Rhodes and Mr. Beit, sat down in the kraal of Lobengula, and persuaded that naked potentate to grant all the minerals in his dominions, with the necessary powers for taking them, for a consideration of £100 a month, one thousand Martini-Henry rifles with ammunition, and an armed steamboat. In the following year the Royal Charter was granted and the British South Africa Company constituted. In 1891 another concession was granted by Lobengula to Mr. Lippert, which amounted to a power to lease and grant land, in considera-

tion of £1,000 down and a rent of £500 a year, in all the territories which might be occupied by the Company, subject to the Company's rights, and to levy "rents, licences, and taxes" on the lands so leased or granted. This concession was acquired by the Company. The Royal Charter gave the Company power to acquire by grant any powers necessary for the purposes of government, and at that time it was apparently intended that any such power should be obtained from the native rulers; but in 1891 a Deed of Settlement was issued which specifically empowered the Company to make laws and ordinances and to levy taxes and raise revenue. In the same year a picked band of pioneers took possession, but it soon became clear that Lobengula was not going to give any assistance, and difficulties grew apace. The hardships, in fact, were very great. The land was new in every sense, and everything had to be done, but what made the work peculiarly hard was that the pioneers—at this time about fifteen hundred in number—were so far removed from civilisation. They were seventeen hundred miles from the coast, and their food cost them £70 a ton. The police force of 700 men was originally costing the enormous sum of £250,000 a year, but by the exertions of Dr. Jameson the force was shortly reduced to forty and the expenditure to £30,000 a year. This was made possible by the vigour of the community itself, which formed a force of five hundred men, three hundred of whom could be mounted, at a cost to the Company of about £4 a head per annum. There was an occasion on which this force distinguished itself. There was a border dispute with the Portuguese, which led to an engagement between forty of the Rhodesians and four to five hundred Portuguese and natives, with the result that the latter suffered heavy loss and fled in confusion towards the coast; the Rhodesians captured the stores and eleven machine guns, and would probably have pursued the fugitives to Beira if they had not been stopped by superior orders. This little affair, which was interesting as showing the ease with which fights can be brought about in such circumstances without any pedantic regard for diplomatic procedure, was settled up to the satisfaction of both sides. The Portuguese incident brought about the building of the railway to Beira, which was constructed by the Company by arrangement with a Portuguese company, and on its completion the cost of goods delivered fell to £10 a ton. After the conquest of Matabeleland in 1893 the Company was permitted to assume the administration of this country. In 1894 an Order in Council was issued, which provided that an Administrator, to be approved by the Imperial Government, should be appointed by the Company to govern the territories, the appointment to be for three years, and also that a Council should

be constituted, consisting of the Judge and three other members who were to be selected by the Company and approved by the Secretary of State. In 1895 came the raid of Dr. Jameson on the Transvaal, followed by an outburst of rinderpest which killed nearly all the cattle in Southern Rhodesia, and rebellions of the Matabeles and Mashonas. The burdens on the Company now increased heavily; mining was disappointing, agriculture hardly attempted. There was much discontent and bitterness among the settlers. The population which was first attracted to Rhodesia was hardly of the kind which is ready to wait with exemplary patience for developments. They went out mostly to find gold; 60,000 claims had been pegged in 1896; and in mining centres results one way or the other are comparatively quick in coming. Miners, like other people, are affected by their pursuits, and usually show a quickness of feeling, irritation or exultation, as the case may be, which is often embarrassing to deliberate administration. It was fortunate that Rhodes possessed exactly the qualities which gave him supreme influence with this community. He swayed them with wonderful power, and it was his eloquent optimism that preserved the settlement through the first and most trying period of its existence.

It was inevitable, however, that the men on the spot should rebel against a system under which the whole government was vested in a London Board. No wisdom, however angelic, on the part of a body of men sitting some 8,000 miles distant, would prevent complaints and agitations in such circumstances. In 1898 a Legislative Council was constituted, consisting of five nominated and four elected members, but as the latter were outvoted with mechanical regularity whenever any difference of opinion arose, it cannot be said that the concession had any pacific effect. In 1902 Rhodes died, and several of the Directors paid a visit to Southern Rhodesia and received deputations. The result was that in 1903 the Legislative Council was increased to seven elected and seven nominated members, presided over by the Administrator, with the Resident Commissioner as ex-officio member; but this enlargement left the two parties in practically the same position. It was an attempt at compromise which settled nothing. The difficulty was that, on the one hand the Company had to make good a heavy deficit, and therefore claimed control of the finances, while, on the other, the people who paid the taxes demanded representation and freely asserted that the expenditure was extravagant. In the meantime the Boer war added greatly to the financial strain. In 1904 the Company sent out a representative to investigate the position, and the report which resulted put the expenditure which had been laid out at over

seven and a-half millions, and treated this as a debt which the settlers owed to the Company. The representative proposed that of the above sum £5,000,000 should be paid to the Company in full settlement, and that the balance should be administered by the Company on public works. This solution was received with a howl of derision, and not only did the settlers repudiate liability for past expenditure and enquire sarcastically what they were to get for the five millions, but they questioned the right of the Company to anything more in the land than the minerals. A delegation to England failed to come to terms with the Company, or to induce the Imperial Government to intervene. But the long lane now began to turn. Politics in such cases turn on economic conditions, and when the banket boom in Mashonaland started, and a great number of small mines came to be worked, most of the discontent vanished for the time being like a lifting fog. Contemporaneously with the improving prospects, the Company took a more liberal line by granting facilities and loans to small miners, and still further reduced the expenditure. In the year 1905-6 the revenue for the first time exceeded the expenditure. In 1907 the Directors paid a visit to the country, and came back full of determination to carry on an active policy of development. This meant more capital, and an endeavour was made in 1908 to increase the capital from £6,000,000 to £9,000,000. This failed, but a sum amounting to nearly a million was raised by the issue of debenture stock, and this additional capital has greatly facilitated operations. The administrative revenue is now likely to exceed the administrative expenditure over and above what is appropriated by the Company commercially.

The cost of living in Southern Rhodesia is very largely a question of railway rates. These rates are really artificial. The natural port of the country is Beira, which is 562 miles from Gwelo as against 1,312 from Port Elizabeth, but when the line to Beira was completed the rates charged were almost the same as to the southern ports, and as the facilities at the latter were greater they secured the business. The reason why the Beira route was not allowed to charge lower rates, proportionate to the shorter distance, was that this would not have suited the Company, the interest of which was mainly to support the Vryburg-Bulawayo line. Then the Company was saddled with the interest on the debenture debt of 4½ millions on the Victoria Falls extension to Broken Hill, which earns nothing towards it, and this annual charge of about £300,000 has to be met by increasing the charges on the southern lines. Thus both the Company and the settlers suffer from the lack of success which has hitherto attended the Broken Hill mines. This trouble led to an application in 1908 to

the Imperial Government for a guarantee of debentures, but, somewhat unfortunately, the memorandum referred to Rhodesia as "rapidly becoming—if, indeed, it may not be already described as—one of the most prosperous Colonies of the British Empire"—a statement which was pounced upon as showing that no such assistance was necessary. The line, however, is in process of extension with the help of Tanganyika Concessions, Limited, to the Katanga Copper Fields (230 miles), and there is good reason to hope that this district will cause an increase of traffic over the whole system. The effect of such business would soon be marked in the reduced cost of living in Rhodesia. Then, looming in the near future, is the railway now being constructed from Lobito Bay, in Portuguese West Africa, which will join the Cape to Cairo line in Northern Rhodesia. Between this and the Beira route it is certain that eventually the traffic will be wrested from the southern ports, but Rhodesia will be the gainer. The Katanga district is believed to be so rich in minerals that four railway routes to it have been projected. Of these the Congo and Lobito lines will eventually be the best placed to secure the traffic. The rails from Rhodesia have reached the frontier of the Congo Free State and will thence proceed to the "Star of the Congo." In the meantime it is very encouraging to find that the net earnings of the whole Rhodesian system showed an increase in the last year (1908-9) of nearly £100,000.

In reviewing the administrative work of the Company one mistake stands out prominently. Far too much of the country has been granted away without any security or even likelihood that it would be worked. There is in the beginning of such things a great temptation to accept big offers, and if they are refused the cry may be raised that capital is being blocked out and development arrested. But if the grantees do not work the land, but simply hold it up till the market value has increased enough to satisfy them, the progress of the country is seriously retarded. It was soon found that mining claims had been too freely granted, and that valuable land was being largely held up. It is an invidious thing to rectify such mistakes by legislation, which imposes further conditions on the grantees, but it had to be done, and an ordinance was passed in 1908 making a certain amount of working necessary to keep claims alive.

The great problem, however, of the respective rights of the Company and the settlers awaits adjustment and the *deus ex machina*. The British South Africa Company, when they set to work to establish in the territories under their control a vigorous, progressive, and self-assertive community of white settlers, ran

much the same risk as Frankenstein did, when he succeeded in endowing his own handiwork with life. The main object of a commercial company must be to earn dividends for its shareholders, and although this particular object was perhaps overshadowed by others in the mind of the original founder of the British South Africa Company, yet the pursuit of it necessarily shapes the policy of the directors. On the other hand, no young community of European origin is ever likely to reconcile itself to the notion that its own enterprise, and the development of the country which it inhabits, should be made to subserve the interests of non-resident shareholders. Hence it is only natural that a study of politics in Southern Rhodesia at the present day should be largely a study of differences between the settlers and the directors. But this must not be taken to mean that the settlers have been selfish and ungrateful and the directors selfish and narrow-minded. Neither charge can be brought with any sort of justice. It is true that Southern Rhodesia repudiated, passionately and indignantly, the suggestion put forward by the Company's financial representative five years ago, that the country should accept an indebtedness of seven and a-half million pounds, five million to be paid over to the company in recouplement of past expenditure and two and a-half millions to be administered by them in trust for public purposes. It is true that on this and on other occasions angry feelings have been aroused and strong language used. It is true that the question of the powers of the elected members in the matter of finance is still a matter of acute controversy, and that an appeal has been made by the Legislative Council, without success, to the Imperial Government to decide certain questions, clearly of fundamental importance, still at issue between the Council and the Directors. But on the other side of the account must be set the extraordinary faith which Southern Rhodesia always showed in Cecil Rhodes, and her strong attachment at the present time to the personality of Doctor Jameson, while the constant wish expressed by the settlers throughout every phase of controversy has been that the London Board should bring themselves into closer touch with the people of the country by personal visits, and by maintaining a local representative with adequate powers. On the other hand, the Directors, if they have put forward financial proposals which were clearly impossible or unacceptable, have done so under the pressure of a most trying responsibility to their shareholders, and the sketch of Southern Rhodesian history given in Mr. Hone's volume is largely an account of a growth in the spirit of concession to local interests and local sentiment. No one who has read anything of Colonial history, who knows anything, for example, of the relations of

Massachusetts and the sister American Colonies to the home government and the directorates of proprietary companies, no one who has any experience of the differences which arise to-day, primarily over matters of finance, wherever popular representation is conceded and popular control withheld, will regard the difficulties which have been experienced in Southern Rhodesia as in any way remarkable, or as reflecting any discredit on the motives or capacity of the parties concerned.

Southern Rhodesia started on its career under the British flag under the influence of an extraordinary fever of unreasoning optimism. The vast difficulties of development, of transport, and of supply were overlooked. Little was known of the real capabilities of the country. Extravagant expectations of immense and early profits sent the shares of the Chartered Company up to a fabulous price. There was bound to be a reaction, bringing disappointment and even ruin in its train. But the intensity of the reaction was aggravated by a succession of disasters—rebellion, plague, and war—which could not reasonably have been anticipated. Looking back on the whole story, the chief cause for wonder is that the set-back has not been more permanent and more complete. From time to time there have been minor “booms,” reminiscent of the frenzy of the original exploitation, and they have been followed, as is the nature of things, by periodic depressions. But the general tendency of recent years has been one of steady advance. Growth in white population, extension of the area of settlement and cultivation, introduction of new products, expanding revenue, increasing railway receipts, all tell the story of a real growth of prosperity, and perhaps the best feature of all is the steady confidence of the people in the land of their choice. The history of nearly all human progress is a history of mistakes, first made and then found out. In Rhodesia two fundamental mistakes were made; but they are beginning to be corrected. Mining was encouraged at the expense of agriculture, and hurried exploitation by big companies was preferred to steady painstaking development by men of limited capital. If big fortunes are not being made to-day in Rhodesia, persistent effort is raising many from a position of anxiety and uncertainty to one of comfort and independence.

We have mentioned above the appeal made to the Imperial Government to act as arbiter between the Legislative Council, as representing the inhabitants, and the directors of the Company. The reply to this appeal, quoted by Mr. Hone, was to the effect that “the questions which His Majesty’s Government had been asked to decide were to a large extent matters which, unless they

could be settled between the parties concerned, did not appear under present circumstances to be susceptible of any binding solution, except by the Courts of Law, and that, even were His Majesty's Government to undertake to express an opinion, they would not be able to compel either side to acquiesce in the decision, if there should be any reason for objecting." Of these and other outstanding questions there is bound to be a settlement before very long; and it is in the consciousness that the present position of affairs is transitory and that Rhodesia is destined for a political future for which it is not yet ripe, that one may seek an explanation of the growing friendliness and mutual forbearance between the nominated and elected members of Council to which Mr. Hone bears witness. When that settlement is undertaken, the Imperial Government cannot assume the position of an independent arbiter, for it is itself a deeply interested party in the transaction. Besides the Imperial Government, the people, and the Company, there is now a fourth party to be considered—the Union of South Africa—in whose constitution a door for the future admission of Rhodesia has already been provided. We are faced with a problem in Imperial development and organization of the most extreme complexity, a problem which does not press for immediate solution, but which cannot be indefinitely postponed. Mr. Hone's temperately written and instructive volume will help many readers to estimate the nature of the factors to be taken into account. He concludes his work by considering on what terms the Company could be bought out by the people. It is obviously impossible to estimate the value of the assets. Mr. Hone considers that the proper course would be to base the negotiations on the capital invested by the Company, and an allowance of a fixed accumulated interest on it; and he urges that "the chartered shareholders have subscribed large sums of money for the acquisition and development of a new British possession, and for this they deserve full recompense, a return of their capital invested, plus a fair and moderate rate of interest for the period that it has been locked up, and compensation for ceding their rights to the people." This is in principle analogous to the proposals of 1904, but if the transaction is regarded as one of purchase and sale it may be observed that the usual business course in like circumstances is wholly different. Investments are unfortunately often unremunerative, and when it seems probable that a considerable amount of capital has been lost, or at any rate has failed for a long time to earn money, no purchaser will buy on the footing of what has been spent. Yet this is what it is proposed that the Rhodesian settlers should do. It is clear that, if it is to be a case of bargaining between the two parties, the actual position of the revenue and

expenditure at the time would be the governing factor. It is further assumed that the Imperial Government would guarantee the whole of the purchase money. If it did, it would presumably require that the amount should be conditioned by the ability of the population to meet the interest. It seems, however, unlikely that the home government would assume any such responsibility for a state, the destiny of which appears to be with the Union of South Africa.

## THE DEVELOPMENT OF PAPUA.

Across Papua. (BY COLONEL KENNETH MACKAY, C.B., M.L.C.  
*Witherby & Co.* 7s. 6d.)

Wanderings Among South Sea Savages. (BY H. WILFRID  
WALKER, F.R.G.S. *Witherby & Co.* 7s. 6d.)

ONE morning, in the year 1883, the Colonial Office was somewhat shaken from its usual calm by the receipt of a telegram, which had not been prefaced by any correspondence, from the Resident Magistrate at Thursday Island announcing that he had set up the British flag in New Guinea and proclaimed the annexation of the Island. Several years before, the question of annexation had been discussed very deliberately. Queensland, in 1874, suggested the idea and the Secretary of State consulted all the Australian Colonies. The replies differed considerably, and eventually the Earl of Carnarvon decided to take no action. A deputation from the Royal Colonial Institute waited upon him to urge annexation. Their chief business argument was a rather curious one, being that New Guinea commanded a supposed new route to China discovered by Captain Moresby. But there was hardly a single Englishman on the Island and there was no definite commercial information of a kind likely to attract enterprise. An Australian proposal to develop the country through a company fell through, and though in 1878 there was a small rush of gold-diggers nothing much came of it. The High Commissioner for the Western Pacific in 1878 suggested annexation, by authorised proclamation, of any parts where a bona-fide settlement had been formed, and this was where the matter was left by the Home Government. There was clearly no substantial settlement at the time, and Great Britain had no disposition to undertake an acquisition which might have cost her dear.

In the correspondence the precedent of New Zealand had been quoted which cost Great Britain twelve millions; and it had been urged that in New Zealand there were only 100,000 natives, while in New Guinea there were probably several millions. The argument

had weight, and certainly in those not very distant days the military dangers from large native populations were held in greater estimation than they are now. The only consideration that really mattered was that if Great Britain did not annex the island some other power would, and that this would be intolerable to Australia. The possession of New Caledonia by France was a thorn in the side of our colonies partly because it brought a rival naval power on the scene, but still more because the island was used as a receptacle for convicts. The dangers which might occur from the escape of such convicts were a familiar topic in Australia; though such is the inconsistency of human nature that on one occasion when a party of them actually did escape to Queensland, the popular sympathy was strongly with them and against surrendering them. In the case of New Guinea it was Germany to whom designs of annexation were attributed, and the danger was strategic in character. Probably the seriousness of the matter from this point of view was overdrawn, and now that Australia is embarking on an active naval policy such apprehensions of exposure to attacks from near stations will die down. But in the eighties they were a great force in Australian politics.

The action of the Resident Magistrate proved ineffective. The Earl of Derby found nothing new in the position of affairs and declined to ratify the annexation. Not long afterwards Germany did annex New Guinea, but whether she had previously intended to do so or was encouraged to do so by Great Britain's refusal is a matter outside the records. There was, no doubt, a rumour at the time of the provisional annexation that Germany was about to take possession, and probably the truth is that the step was being considered and that the decision was expedited or influenced by the knowledge that Australia was pressing for annexation. The action of Germany, of course, occasioned great excitement in Australia and a prolonged diplomatic tension at home. Eventually a compromise was arrived at by which New Guinea, or rather such portion as was not claimed by the Dutch, was divided between Germany and Great Britain, and the neighbouring Pacific was demarcated between the two Powers by a zig-zag line which, it is safe to say, few people now remember. The settlement of the case, considering the feverish circumstances under which it was made, has worked satisfactorily. Australia has profited commercially by German enterprise in the Pacific, and has had no reason to fear the establishment of military bases there. The island itself has, so far, proved valueless financially, and the German colony requires a considerable subsidy. There are still repinings in Australia that the whole island was not secured, but it is at any rate realised, after several years of experience, that it has not yet been possible to utilise it as a working white man's country. But if the island has not so far materialised as a mere

business proposition it is full of beauty and interest. The explorer may find much to do, and the still virgin and active Mount Victory offers "a field still open for any adventurous soul with a leaning towards cremation." The difficulties of locomotion and transport are exceedingly severe, and one result of this is that travellers have eked out their actual experiences by largely drawing the long bow; in fact there has been more literary fraud in connection with New Guinea than any other place. To this the natives have themselves contributed, as whether, from an artistic sense or otherwise, they so much prefer the romantic story to the plain fact that telling the truth is said to be a lost art north of Cooktown. The extension of civilised administration, however, has brought in its train a series of matter-of-fact official reports, and the two books which have been recently written by Colonel Mackay and Mr. Wilfrid Walker record the experiences and impressions of the authors in a very straightforward way. Neither of them attempts to discuss the commercial prospects. That topic is left to the official report of the Royal Commission of which Colonel Mackay was Chairman. The desire of the Commonwealth is to encourage white settlement, and there is no doubt that there is plenty of gold in the island and that a variety of valuable products can be cultivated. Money, however, must be provided if the possession is to be developed for these purposes, and, until it is, the officials are trying to make bricks without straw. The Yodda Valley has long been frequented by miners and gold is easily got; but the climate is bad, provisions dear, and the natives treacherous. The men have to work in bands with their rifles handy, and a short time since two were speared in the legs and carried off to a native village, where they were roasted alive over a slow fire and eaten. Their death was avenged by a band of miners who gave no quarter, but it is not surprising to find that there are now only about fifty miners in the district and that most of them are beginning to leave. Mr. Walker explained that the Papuans as a rule do not torture their prisoners for the mere idea of torture, "though they have often been known to roast a man alive for the reason that the meat is supposed to taste better thus." Whatever the reason, it comes to pretty much the same thing for the victim, and the dread of such cannibalism is no small bugbear to the white officers and settlers. To quote Mr. Walker further: "We had learnt that this Dobodura tribe had a system of torture that was brutal beyond words. In the first place they always try to wound slightly and capture a man alive, so that they can have fresh meat for many days. They keep their prisoner tied up alive in the house and cut out pieces of his flesh just when they want it, and we were told, incredible as it seems, that they sometimes manage to keep him alive for a week or more and have some preparation which prevents him from bleeding to death.

“Monckton advised both Aoland and myself to shoot ourselves with our revolvers if we saw that we were overwhelmed, so as to escape these terrible tortures, and he assured us that he should keep the last bullet in his own revolver for himself. This was my first taste of warfare. Monckton had had many fights with Papuans, and Aoland, besides, had seen many severe engagements in the Boer war, but he said he would rather be fighting the Boers than risking the infernal tortures of these cannibals. It all, somehow, seemed unreal to me, and I could hardly realise that I was in serious danger of being tortured, cooked and eaten. It is impossible to depict faithfully our weird surroundings. We chatted on for some time, and tried to cheer each other up by making jokes about the matter, such as ‘This time to-morrow we shall be laughing over the whole affair,’ but the depressed tone of our voices belied our words, and it proved to be but a very feeble attempt at joking.” In the end the white party killed a good many natives, but recognised the fact that they were not numerous enough to hold their own, much less to punish these brutal tribesmen. It is clear that much fighting and no little expense will be necessary before the possession can be made safe. One of Colonel Mackay’s first sights on landing at Port Moresby was a gang of some twenty prisoners in leg-irons, some of whom were “waiting trial for the brutal murder of the only vegetable grower in the place”—which does not sound encouraging for the honest agriculturist,—and “chatted and laughed as if fresh vegetables were neither here nor there in their scheme of life.”

The most curious people in Papua are the Ahgai-ambo, a semi-aquatic tribe, who were described as follows by Sir F. Winter, when acting Governor of British New Guinea: “The Ahgai-ambo have for a period that extends beyond native traditions lived in this swamp. At one time they were fairly numerous, but a few years ago some epidemic reduced them to about forty. They never leave their morass, and the Baruga assured us that they are not able to walk properly on hard ground, and that their feet soon bleed if they try to do so. The man that came on shore was, for a native, middle-aged. He would have been a fair-sized native, had his body from the hips downward been proportionate to the upper part of his frame. He had a good chest and, for a native, a thick neck; and his arms matched his trunk. His buttock and thighs were disproportionately small, and his legs still more so. His feet were short and broad, and very thin and flat, with, for a native, weak-looking toes. This last feature was still more noticeable in the woman, whose toes were long and slight and stood out rigidly from the foot as though they possessed no joints. The feet of both the man and the woman seemed to rest on the ground something as wooden feet would do. The skin above the knees of the man was in loose folds, and the sinews and muscles around the knee were not well developed. The muscles of

the shin were much better developed than those of the calf. In the ordinary native the skin on the loins is smooth and tight, and the anatomy of the body is clearly discernible; but the Ahgai-ambo man had several folds of thick skin or muscle across the loins, which concealed the outline of his frame. On placing one of our natives, of the same height, alongside the marsh man, we noticed our native was about three inches higher at the hips.

"I had a good view of our visitor, while he was standing sideways towards me, and in figure and carriage he looked to me more ape-like than any human being that I have seen. The woman, who was of middle age, was much more slightly formed than the man, but her legs were short and slender in proportion to her figure, which from the waist to the knees was clothed in a wrapper of native cloth.

"The houses of the near village were built on piles, at a height of about twelve feet from the surface of the water, but one house at the far village must have been three or four feet more elevated. Their canoes, which are small, long and narrow, and have no outrigger, are hollowed out to a mere shell to give them buoyancy. Although the open water was several feet deep, it was so full of aquatic plants that a craft of any width, or drawing more than a few inches, would make but slow progress through it. Needless to say that these craft, which retain the round form of the log, are exceedingly unstable, but their owners stand up in them and pole them along without any difficulty.

"These people are very expert swimmers, and can glide through beds of reeds or rushes, or over masses of floating vegetable matter with ease. They live on wild fowl, fish, sago and marsh plants, and on vegetables procured from the Baruga in exchange for fish and sago. They keep a few pigs on platforms built underneath or alongside their houses. Their dead they place on small platforms among the reeds, and cover the corpse over with a roof of rude matting. Their dialect is almost the same as that of the Baruga. Probably their ancestors at one time lived close to the swamp, and in order to escape from their enemies were driven to seek a permanent refuge in it."

Colonel Mackay writes in a natural and breezy manner, and supplies the personal impressions which are usually lacking in an official report but are necessary to a vivid appreciation of a country. His judgment of Papua's future seems to be that many parts of it are extremely well adapted for tropical produce, and that splendid possibilities lie waiting for the time when the world is hungrier and more crowded than now.

## HURRICANES AND HURRICANE RELIEF.

BY HIS HONOUR F. H. WATKINS, I.S.O.

### PRELIMINARY REMARKS.

FEW among those who are born or live for any considerable period in the West Indies are fortunate enough to escape the trying and disastrous experience of one or more hurricanes, and it is therefore a matter for surprise that so little knowledge is possessed by most residents in these islands about the phenomena attending these periodical visitations, especially when it is considered that even an elementary acquaintance with the conditions controlling these storms would, in many cases, be sufficient, if not to avert entirely, at least to minimize, loss of life and property on such occasions. As recent events have cogently proved, such knowledge can be of the utmost practical value, and it is with this consideration that these notes, based on the study of well-known authorities and on the experience gained by having passed through six hurricanes, are offered for perusal, with the hope that further interest in a subject so important may be awakened. Those desirous of becoming more intimately acquainted with the history, origin, movements and physical features of these terrible atmospheric disturbances will do well to study the monthly reports of the U.S. Weather Bureau, the special report of that department by E. B. Garriott (Bulletin H), and by W. H. Alexander (Bulletin No. 32), Elementary Meteorology by W. M. Davis, Cyclonic Circulation, and the Translatory Movement of West Indian Hurricanes by Vines, the Forms of Water Clouds and Rain by J. Tyndall, and the Handbook of the Hurricane Season by Bishop Westerby.

### GENERAL DESCRIPTION.

Revolving Storms (Cyclones (kuklos, a wheel) in the West Indies, Typhoons in the Pacific, &c.) are so called because they revolve round an area of low pressure in which there is relatively little wind, while at the sides of this calm centre the pressure of the air, as indicated by the barometer, is very great, especially on the quarter towards

which the disturbance is moving. The winds approach the centre in spirals; the circular and centrifugal movements increasing every moment. The air circulating round the sides rises to the cloud stratum immediately above the vortex, when the air, flowing out on all sides and cooled by expansion, causes the vertical eddy to be surrounded by a thin sheet of rain, extending on an average 150 miles (some times as much as 500 to 700 miles) in front of and 100 miles at the back of the storm. The vortex varies in diameter from twenty to several hundred miles, and travels in its progressive movement westward about 300 miles a day.

Hurricanes form below the Tropic of Cancer in the Northern Hemisphere. Being cyclonic in nature, these storms cannot develop while the doldrums or calm areas of the Atlantic are close to the equator, where the inblowing currents do not unite in causing a systematic vortex, but only when the doldrums, after the commencement of the warm weather experienced at the disappearance of the trades, have sufficiently advanced northward, usually between 5 and 15 N. to allow of convectional action, hereinafter explained, which takes place, as a rule, in July or at the commencement of August. Although hurricanes have been known to arrive in nearly every month of the year, August, closely followed by September, marks the period of maximum activity of cyclonic disturbances.

#### CAUSES AND ORIGIN OF HURRICANES.

Before discussing the origin of cyclonic storms, it is convenient to examine briefly the general principles of the causes of the production of wind. The great principle to be grasped is that heat expands and the heated air is lighter than cool air. When, therefore, the air expands and grows lighter it is impelled upward by the cold or heavier air rushing to take its place. The heated air in any region of the earth moves towards some colder quarter, while the cold air moves to a warmer zone. Since the air is generally speaking warmer at the equator and coldest at the poles, the air from the equator blows towards the poles as an uppercurrent and the air from the poles flows beneath along the surface of the earth, although, owing to the rotation of the earth, not in a direct course. It must be remembered that the earth turns on its axis from W. to E. at about 1,000 miles an hour at the equator, which velocity gradually diminishes towards the poles, and that the air, even when apparently at rest, is moving with great rapidity. So long as the air remains in this relative condition of rest, the movement of the airs is imperceptible, but it becomes effective the moment the air is impelled to a latitude having a higher or lower rate of revolution. In the Northern Hemisphere the polar currents, blowing about two miles in depth as surface winds, are known as the Trade Winds, while the currents,

setting from a lower equatorial region to a higher latitude give rise to S.W. winds. The trade winds die off as the season advances and the air in the northern latitudes becomes warmer. A similar phenomenon connected with warm and cold currents of air, is observable in the sea and land breezes of the West Indies. Since the land becomes heated more rapidly than water, and ascending currents of air rises from the land soon after sunrise and causes the colder wind to blow in from the sea; while, after sunset, since the land also cools more rapidly than the sea, the warmer currents ascend from the water and the cooler heavier air blows out from the land.

So long as normal conditions of hot and cold air prevail hurricanes do not occur, but atmospheric disturbances are produced in those months when any area becomes saturated with heat and when the consequent ascending current is kept in motion by the abnormal rarefaction of the air above by means of the caloric given out by the water condensed during its ascent. To understand the cyclonic nature of hurricanes it is only necessary to observe how water, as it becomes heated in a vessel placed over a fire, is pushed upwards by the colder, heavier water falling down the sides by the force known as convection. The inflowing currents at the bottom and the outflowing currents at the top of the vessel are connected by the ascending currents in the centre and by the descending currents at the sides, which form a complete cyclonic circuit. The primary tendency of the colder air to take the place of that ascending in the heated air is deflected by the rotation of the earth, so that an easterly direction is imparted to the wind in the northern half of the area, and a westerly direction in the southern half, the combined effect producing a circulation round the centre of lowest pressure from W. through S.E. and N. round again to W., that is, against the movements of the hands of a clock.

So long as the ascending current can be supplied with air saturated with vapour, rarefaction continues, as do also the ascent of the air in the centre of the storm and the rush of the air to take its place. The strength of the storm depends upon the quantity of heat and vapour supplied by the currents below, for what especially causes the tremendous forces generated during hurricanes is the heat energy, which has been locked up in a latent condition in the water vapour and is set free as the water is condensed. Since it is to this latent energy that hurricanes owe their strength, they never reach unusual violence unless the air is nearly saturated with vapour, while, on the other hand, cyclones originating in the Atlantic East of the Caribbean Sea do not lose their force until they recurve and take a N.E. direction towards a colder atmosphere.

Besides their rotary movement, hurricanes have a progressive movement, travelling within the tropics from E. to W., and continuing in the temperate zone, after recurving towards the pole, from W. to E.

The track taken is held by some to be in close relation with the course of atmospheric currents, while others contend that the storm centre moves towards the region of greatest precipitation. The track thus followed is called the path of the storm, the portion of the hurricane to the right of the path being known as the right hand circle, and that on the left as the left hand circle. In the Northern Hemisphere the right hand circle is more dangerous. Until the hurricane reaches the apex of the parabola or recurving point, which is between 75 and 95 Long. W. and 15 to 25 Lat. N., and as a rule near the Bahamas in August and September, the progressive velocity increases steadily, the average rate, as above, being 300 miles a day. At the recurving point the velocity decreases sometimes to one or two miles an hour but rapidly increases on its eastward track, attaining at times a maximum of 35 miles an hour. The hurricane after recurving is thus speedily carried into more temperate regions, "where it assumes more and more the characteristics of a cyclone by spreading over a larger area and losing its violent nature as it journeys northeastward, hence it may be said that the hurricane bears in itself the seeds of its own destruction." During the recurving of the storm, islands like Grand Turk, which often lie within the parabola, feel the effects of the hurricane successively on the south, west and north.

#### WARNINGS OF APPROACHING HURRICANES.

Several readily accessible means are at hand for ascertaining the formation and approach of hurricanes, provided intelligent use is made of them and of one's powers of observation. Chief among these means are the movements of clouds, the appearance of the sea, the barometer and the thermometer.

#### CLOUDS.

So important and useful are clouds, the *Fliegende Wolken*, *Segler der Luft* of the dream of Maria Stuart or the valkyries of the air, in affording valuable information as to atmospheric changes and disturbances, that it is almost a matter of necessity that an elementary knowledge of the different cloud formations be acquired, and for this reason the following brief notes on this subject are introduced.

There are four primary forms of clouds :—

- Cirrus
- Cumulus
- Stratus
- Nimbus

*Cirrus Clouds*, which take their name from their resemblance to a lock or curl of hair, and are commonly called mare's tails or cat's

tails or Pele's Hair, are composed of isolated feathery masses of cloud particles from 15,000 to 30,000 feet in the higher regions of the atmosphere, so far above the surface of the earth that these particles are generally in the condition of ice crystals. It is chiefly to do with Cirrus clouds that haloes appear round the sun and moon. There are two distinct forms of Cirrus clouds. The first form, like feathery shafts, commence to appear when a cyclone is 300 to 400 miles away and converge to a spot on the horizon, indicating the centre of the disturbance and giving warning of a storm of small diameter but of considerable force, while the second kind are of zone shape and of large diameter, forecasting a storm of moderate strength. The upper currents of Cirrus clouds afford more information as to its situation and force while the storm is still at some distance, but, when the vortex is near at hand, the movements of the lower clouds are more reliable guides in determining the position and direction of the calm centre.

*Cumulus or Heap Clouds* consist of dense masses of cloud formation collected in the lower regions of the atmosphere (4,500 to 7,500 feet) where the amount of water vapour is greatest, and are humpback on the top with flat bases. They are, as a rule, produced by the ascending daily air currents carrying the warm moisture to the upper regions, where the clouds are chilled by the cold of elevation and expansion.

*Stratus or Layer Clouds* occur in the form of horizontal bands or layers, and are due to the gradual settling of the other clouds, for which reason they are common in the early morning and late evening, when the ascending currents of air are weak.

This form of cloud is least elevated of all, being under 3,000 feet, and often becoming fog by falling to the surface of the earth.

*Nimbus, or Rain Clouds* are dense masses of formless clouds with ragged edges, through which are often seen Cirro-Stratus clouds. When the mass of nimbus is broken up into small fragments, or if portions float below the cloud, they are called "scud."

The chief secondary forms of clouds are:—

Cirro-Stratus

Cirro-Cumulus

Cumulo-Stratus

*Cirro-Stratus Clouds* are whitish layers, usually forming a diaphanous veil and often giving the sky the appearance of a mackerel's back; hence such a sky which indicates approaching rain, is known as a mackerel sky.

*Cirro-Cumulus Clouds*, known as "Wool Sacks," are Cirrus clouds arranged in little round masses like small cumulus and point to dry weather.

*Cumulo-Stratus Clouds* resemble mountain masses with a stratus base.

## DIFFERENT PHASES OF TYPICAL CYCLONIC DISTURBANCES.

There are several distinct phases in hurricanes, and those most prominent are :—

- (1.) The anti-cyclonic period.
- (2.) The period more immediately preceding the arrival of the vortex.
- (3.) The passing of the vortex.
- (4.) The recession of the vortex.

I. During the first phase the meteorological elements follow in reverse order the normal climatic conditions of the season of the year and those in the subsequent phases of the storm. The distinct features of this phase are :—

- (1.) An unusual rise in the barometrical readings.
- (2.) Cool weather, the thermometer falling several degrees below the normal.
- (3.) Cloudless sky of deep indigo tint.
- (4.) Anti-cyclonic winds, and the disappearance or disturbance of the land and sea breezes.
- (5.) An ocean swell from no perceptible cause.

II. In the period immediately preceding the arrival of the vortex may be observed :—

(1.) Gradual fall in the barometer with irregular fluctuations. The fall becomes more rapid as the calm centre comes in close proximity.

(2.) An increasing ocean swell.

(3.) Oppressing heat with light variable breezes developing into a stronger wind from a direction between N.W. and N.E.

(4.) A great change in the upper strata of the air, with the appearance of a reddish and purplish sky covered with what is known as the "cirrhose veil." This phenomenon, according to Father Vines, "is always observable when the outermost part of the hurricane begins to invade the place of observation.—The transparent and blueness of the sky characteristic of the past anti-cyclonic weather is succeeded by an opaqueness or veil called the cirrhose veil, so extremely subtle in the beginning as to render it almost imperceptible. Notwithstanding its subtlety, this veil exerts a very great dispersive power on the solar rays, its principal feature being the almost entire absorption of all the prismatic colours except red. These powers of dispersion and absorption are chiefly remarkable when the solar rays are compelled to pass through a great portion of the atmosphere. Consequent upon this, the rising and setting of the sun are attended by an anomalous colouration of the sky, ending or beginning when the altitude of the sun, is on an average, 15°, the colouration increasing as the altitude decreases." This cirrhose veil gradually changes as the hurricane approaches. At first, its

colour is of a whitish milk tint, but, afterwards, it appears more opaque and assumes a hue rapidly growing darker and darker, when the arc is called the bar of the hurricane which increases gradually in altitude to about  $20^{\circ}$ , but the base is concealed below the horizon.

(5.) Shortly after the bar is formed on the horizon, Nimbus clouds begin to overrun the sky in inexhaustible succession. Short intermittent showers fall and the rain sensibly increases. At first the rain is very light, of a spitting character, is accompanied by squalls of a velocity of 40 to 55 miles an hour, while the mean velocity of the wind outside of the squalls is from 35 to 40 miles an hour. As the centre approaches nearer and nearer the rain becomes continuous, although irregular in quantity, the showers succeeding each other at shorter intervals attended by furious gusts from 100 to 120 miles an hour, and now is heard the ominous hurricane whistle, which once heard can never be mistaken. Certain features connected with these showers and gusts derive special notice. In the first place, the velocity of the wind augments considerably at the beginning of, and during, the showers, for, while the wind in the body of the hurricane rarely exceeds 65 miles an hour, the wind in the gusts increases to 100 to 120 miles an hour. The duration of the showers is from one to two minutes, while the gusts last but a few seconds. Again, during the showers the wind (supposing you are facing it) always shifts to the right from  $45^{\circ}$  to  $90^{\circ}$  (four to ten points) so that if wind is blowing from N. before the shower, it will blow N.E., E.N.E. or E. during its continuance, the greatest variation corresponding with the greatest force. During the gusts the barometer oscillates violently.

(6.) While the hurricane is still at some distance sand and leaves are blown in spiral forms like miniature whirlwinds.

#### RULES FOR DETERMINING THE POSITION AND DIRECTION OF AN APPROACHING HURRICANE.

As soon as it has been ascertained that a hurricane is in the process of formation, it is important to determine its position and direction and, for this purpose, the following rules will be of great assistance :—

(1.) If you face the wind and it shifts to the right from N. to E., S. or W., you will be on the right hand semicircle and the hurricane will pass to the south ; if, however, the wind shifts to the left from N. to W., S., E. and N., you will be on the left semicircle and the hurricane will pass to the north.

(2.) If the bar remains stationary on the horizon, while the barometer descends rapidly and the velocity of the wind and the showers continue to increase, you are in the direct path of the storm. The more tenaciously the surface winds cling to the N., the greater the probability also of the centre passing directly over you.

(3.) When the storm commences, the centre will be from eight to ten points on the right hand of the wind, about ten points when the barometer has fallen 3-10 of an inch, and about eight points when it has fallen 6-10 of an inch or upwards.

(4.) If the movements of the wind take place rapidly the centre is not far off, on the other hand, if the changes are slow the vortex is either at a distance or is recurving.

(5.) As has been stated, the Cirrus clouds radiate from a divergence focus which marks the position of the vortex.

III. The features of the vertical calm are:—

(1.) An abatement in the velocity of the wind.

(2.) The calm in the vortex is relative, for the wind is seldom less than six, though never more than ten, miles an hour, and this calm is interrupted by sudden gusts, of 20 to 30 miles in velocity, which continue for only a few seconds and are variable in direction blowing from all parts of the compass.

(3.) The sky overhead is clear.

(4.) The barometer, after making a sudden drop, which records the minimum reading, oscillates violently for a few moments, remains stationary for a time, and then begins gradually to ascend.

IV. The principal phenomena making the recession of the vortex are:—

(1.) The wind suddenly increases from six to ten miles an hour to gusts of 80 to 90 miles an hour. These gusts are especially to be dreaded on the sea on account of their unexpected arrival.

(2.) The wind blows from the quarter diametrically ( $180^\circ$  or 16 points) opposed to the direction of the gusts immediately preceding the period of vertical calm. At times these winds are of greater intensity than those in front of the cyclone, the axis of the storm then being, as a rule, inclined from W. to E.

(3.) Shortly before, or simultaneously with, these gusts, the barometer continues to rise appreciably and ascends until the hurricane is passed.

(4.) Shortly after the gusts appear the showers recommence but with less intensity before the calm and, as the vortex recedes, all the other phenomena, observed in the second phase, recur in exactly the reverse order of succession.

#### PRECAUTIONS TO BE TAKEN ON LAND AND AT SEA.

##### I. On Land.

About the middle of July have a thorough examination of shutters and fastenings, and have number painted on the shutters corresponding to those on the doors or the windows to which they are attached, so that when warning of an approaching storm is

given barring up can be done with as little delay and confusion as possible.

(2.) When barring up a house, begin with the side likely to be exposed first to the hurricane, that is N.E., as a rule, before the vortex is passed and then pay particular attention to the S.W. side. If the centre is to pass to the south, secure the N. and E. sides, if to the North, the N. and W. sides.

(3.) During the vertical calm open up the north side for the purpose of ventilation.

#### II. At sea.

The following are among some concise rules to be observed during revolving storms in the Northern Hemisphere which are published by the Hydrographic Department of the Board of Trade :—

(4.) “ If the seaman has reason to think that his vessel is in the direct path of the storm, he should run with the wind on his starboard quarter until the barometer has ceased falling. If she is in the right hand semicircle, she should remain hove to on the starboard tack ; if she is in the left hand semicircle, she should run with the wind on the starboard quarter.

(5.) “ Should a vessel not have sufficient room to run in the least dangerous semicircle, she should heave to on the port tack.

(6.) “ If in a harbour or at anchor, the seaman should be just as careful in watching the shifting of the wind and ascertaining the direction of the centre, as by so doing he will be able to tell on which side of the storm he is situated and be able to act according to circumstances.

(7.) “ Should the centre of a storm pass over a vessel, the wind, after blowing furiously in one direction, ceases for a time and then blows with equal fury from the opposite direction. This makes a confused pyramidal sea, which is especially dangerous.”

#### DISTRIBUTION OF HURRICANE RELIEF.

Hurricanes, though frequent and inevitable visitants of most of the West Indian islands, involve a more or less long departure from normal conditions, and entail loss of life and property and absence of productive employment owing to the interruption to the carrying on local industries. Chief, therefore, among the problems to be faced after similar calamities are the temporary feeding of the destitute, the temporary and permanent housing of the homeless, the provision of employment to enable sufferers to resume their means of livelihood and relief to those who have lost the bread-winners of the family ; in other words, to restore normal conditions and to prevent, as far as it is practicable, the ensuing demoralisation which is productive of more lasting harm to the community than material lost.

Immediately after a hurricane the question of providing food and shelter at once has to be confronted; with regard to shelter, much depends upon the number of public buildings, schools, etc., left standing, and it is important to see that effective measures are taken for the separation of the sexes and for the observance of elementary sanitary precautions. Some of those taking advantage of the shelter given should be employed in keeping the buildings and surroundings clean. In Montserrat, in 1899, tents were supplied as shelters by the military authorities of St. Lucia.

It is, unhappily, a common belief among the lower classes in the West Indies that it is the duty of the Government to provide food gratuitously to everyone after all tropical disasters, and it is essential from the very first to disabuse their minds of such an erroneous idea, for the sight of free food being distributed seems, in many instances, to act as much as a demoralising stimulant as alcohol. A little firmness in this particular at the commencement will prevent much trouble and misunderstanding later on. Under no consideration should food be given gratuitously, except in the case of those unable to work, and remuneration for relief works should not be given in cash but in the form of tickets upon stores or shops where food can be obtained at all hours, and the danger of crowds gathering round relief centres is avoided. The rate of remuneration given for relief work should not be such as to compete with the wages ordinarily paid to labourers and others, but on such a scale as will enable the recipient to maintain himself and his dependants in food until he can find an opportunity of resuming his regular work. As a rule, two-thirds of a labourer's pay should be allowed to those with a family to support and one-half to single men and women, but much depends upon whether ground provisions are scarce, or whether the food consumed at the time has to be imported. Relief centres for the distribution of food are open to the objection that they are provocative of scenes of confusion and disorder, and that they tend to encourage the idea that food is to be obtained without work, whereas, if the recipients of relief are able to obtain their daily supplies in the ordinary way through the stores, they are more likely to lose the demoralising desire for free food and to be willing to return to their ordinary occupations. The prices at which all kinds of food (alcohol excepted) are to be thus obtained, should, of course, be arranged with the storekeepers upon whom orders are given, so that no advantage can be taken of those presenting tickets. This system of distributing food, besides diverting the minds of the labourers from the abnormal conditions existing, has the further advantage of helping the storekeepers to maintain their usual stock of imported goods and of removing from the latter the temptation of raising the prices of their goods to an exorbitant extent during

a period of scarcity. Where supplies of food are sent from outside, it is also better for those in authority to hand them over for distribution in the manner above suggested, to the storekeepers, who should be given a commission upon the amount of the goods thus disposed of, and for the receipts from the sales to be paid into the general relief fund.

Generally speaking, there are, for some time after a hurricane, numerous ways for providing work, namely, clearing debris, opening up roads, restoring huts moved off their foundations, while carpenters can be usefully employed in rendering habitable houses unshingled or slightly damaged so as to relieve the congestion at the shelter centres, and masons will be required for repairing culverts and small bridges. After the more urgent preliminary works are completed, care must be taken to guard against funds being wasted upon unnecessary labour and to see the expenditure devoted either to useful and productive public works or, better still, in aiding, wherever practicable, those employers of labour who have suffered in the disaster to resume the employment of those dependent upon them for work. In the Turks and Caicos Islands the saltpond owners, who had had to face a succession of disastrous wet seasons and were quite unable to repair the damage to their ponds sustained in the hurricane of 1908, were enabled by a grant from the public reserve funds to employ their labourers in placing their ponds in thorough repair. This method of relief gave, at once, opportunity for present and future productive work, benefitted the sufferers of all classes, and solved the perplexing question of employment, which, the longer unanswered it remained, increased more and more daily the danger of demoralisation among the labourers.

Immediately after a disaster likely to call for special measures and relief, it is wise to obtain, before time is allowed for considering how the amount of losses can be conveniently exaggerated in the hope of assistance, a description of the damage sustained by each individual from policemen or other reliable persons detailed for that object.

When provision has, in the first instance, been made for the primary requirements of food, shelter and temporary employment, the attention of those responsible for the distribution of the funds available for relief purposes has to be directed to the more permanent assistance of those who have sustained loss of property or who have been deprived of the support of the bread-winner of the family. In this particular, the following passages of a preliminary report of the Assistance Committee, appointed for providing houses and means of support to the survivors of the earthquake in Kingston, are deserving of careful consideration, coming as they do from a body coping with the results of an appalling catastrophe, entailing losses of every description, and able to profit in their action by the

experience gained in the distribution of relief after the Jamaica hurricane of 1903.

"The Committee," says the report, "on assuming their functions, found themselves in the position of administrators of a charitable trust, their duty being to interpret and carry out, to the best of their judgment and ability, the intentions of the contributors of the Assistance fund. They therefore deemed it right to proceed as nearly as possible as they would have proceeded had they been private persons dispensing their own money in charity for the purposes prescribed by the Assistance Committee Law with the general and governing aim of repairing the crippling damage inflicted by the earthquake on the city and community of Kingston. They did not hold themselves under any quasi-legal or mechanical obligation to observe as between cases in the same class a superficial uniformity in their awards, nor could they regard the mere fact that an individual had suffered loss, even severe loss, by the earthquake as necessarily entitling him or her to any share of the funds. They had to investigate and exercise discrimination and constantly to control their procedure by reference rather to the intentions and desires of the donors than to the expectations of applicants for assistance. And they regarded the intentions of the donors as being rather to provide for the future than to attempt to redress the past."

Money was not only allowed by the Assistance Committee for the restoration of houses, but was also applied in all deserving cases where statements of loss were received in respect of (a) loss of occupation (b) injuries and disablement (c) loss of bread-winners and (d) loss of any other source of income not specified. Grants, however, were not given to persons on account of their having lost furniture, clothing, plate, jewellery, cash or other personal property, but, in cases where persons were found to be destitute, the provision of absolutely necessary furniture, such as bed and bedding, was authorised. The provision for widows and orphans was considered in the first instance and was given in such amounts as to preserve the beneficiaries from absolute destitution, and then grants were allotted for the restoration of houses on a scale varying from one-tenth of the amount of the damage calling for repair to the full amount in the most necessitous cases.

In the smaller West Indian Islands more especially, it is desirable that all subscriptions and other forms of relief, as well as all disbursements made, should pass through the public treasury accounts on vouchers required by the financial regulations of Crown Colonies and be subjected to strict audit, the wages to labourers employed on public or private relief works being paid to the recipients in presence of responsible public officers.

As earthquakes, hurricanes and eruptions are the natural obstacles to unimpeded progress in the West Indies, it seems but reasonable

that adequate provision in the form of systematic insurance should be made to enable all concerned to deal expeditiously with the consequences of these inevitable periodical visitations by reserving a certain proportion of the public revenue for this purpose. The amount of revenue to be earmarked to meet such contingencies would naturally be determined by the average period between the disasters in individual islands and should eventually be raised to a sum equal to the average annual revenue. The existence of such an insurance fund, which is justifiable on the same grounds as the expenditure on armaments is deemed necessary by larger nations as a precaution against foreign aggression, would prove of inestimable benefit to all classes of inhabitants, for both employer and employee could, with equal justice, participate in the times of necessity, in the distribution of funds to which they had contributed. The chances of undeserving persons obtaining relief would, moreover, be materially reduced because members of local committees would be more reluctant in recommending grants from moneys in which they were more personally interested. As has already been said, the demoralizing after-effects of the distribution of gratuitous relief have inflicted more lasting evil on the West Indies than the material losses of hurricanes and similar calamities, severe though those losses have often undoubtedly been. The custom of trusting invariably to outside assistance on such occasions and of what is vulgarly known as "passing round the hat" on the slightest provocation, has too long prevailed. Much as the ever present feelings of sympathy and ungrudging and lavish assistance from the Mother Country and from sister islands, which, in their turn, have experienced like catastrophes are to be appreciated, this reliance on extraneous aid is not conducive to healthy effort or independent character, qualities unfortunately lacking to an appreciable extent in the West Indies.

Disasters of appalling magnitude will, at times, occur when local effort is paralysed and unable to meet adequately the situation; but every endeavour should be made to discourage appeals for outside generosity, even for the very selfish consideration of the danger of crying "Wolf" too often. In view of the frequency and inevitableness of such emergencies, each island should be prepared with some rough scheme of action for meeting with the exigencies of the moment. The existence of a substantial reserve fund enables such a scheme to be drafted on definite lines and, by the knowledge of what funds are available, facilitates prompt and economical action which otherwise is impossible in the uncertainty as to the ultimate response to appeals to sources of fluctuating sentiment and sympathy.

## BANKING IN WEST AFRICA.

SEVENTEEN years ago all the West African possessions of the British Empire were entirely without banking facilities. A standard money currency was unknown to the millions of natives inhabiting the coast line and hinterland of the British West African Colonies, and practically the whole trade of those Colonies was conducted upon a system of barter.

The only use for a money currency at this period was for the payment of Customs duties to the Government by the European merchants. Even for this purpose money played but an insignificant part as the Government were in the habit of accepting from all the more important commercial houses drafts issued by themselves on their European houses for the payment of the greater portion of the Customs duties, although this method of payment was obviously undesirable from a sound financial standpoint.

In the year 1892, the African Banking Corporation of London opened the first bank in West Africa at Lagos, now the capital town of Southern Nigeria.

It is impossible for those not intimately acquainted with West Africa, and the characteristics of the native inhabitants, to appreciate the difficulties which the establishment of a bank in that country involved. The African Banking Corporation, after an experience of just over twelve months in Lagos, were glad to retire from their venture, and the lack of success which attended their experiment is not difficult to explain. The directors of the African Banking Corporation, although widely known and highly respected in London and South Africa, were unknown personalities to the West African native. In order to achieve success in West Africa, it was imperative that any bank opening there should have as its promoters and local representatives men personally known to and respected by the natives themselves.

To Sir Alfred Jones, K.C.M.G., the credit must be given for being the founder and creator of banking in West Africa.

In the year 1894, subsequent to the withdrawal of the African Banking Corporation from Lagos, Sir Alfred Jones (then Mr. A. L. Jones), the senior partner of the great West African shipping firm of Elder, Dempster & Company, founded the Bank of British West Africa, Limited. The appearance of his name (a household word in West Africa) upon the directorate immediately commanded for the bank the respect and confidence of the natives. Thus the successful flotation was made of what was to become the pioneer bank in West Africa, an institution destined to be the means of introducing a standard money currency throughout the length and breadth of our West African Colonies.

From its inception, the Bank of British West Africa was entrusted with the Government account, and this gave the natives added confidence in the concern, as it was regarded practically as a Government department.

Looking back upon the early days of banking history in West Africa, it is interesting to remember the hostility which was at first manifested by the large European mercantile houses to the advent of a bank. Their attitude, however, is not difficult to understand when it is remembered that almost all of the trade was in the hands of a very few powerful firms and that, as practically the whole of the trade was conducted on the barter system, at enormous profits to the European merchants, the introduction of the English silver currency (which is legal tender to any amount in British West Africa, and which has been from 1894 to the present time the standard currency) was not welcomed by them.

It is an incontrovertible fact, however, that the establishment of a money currency in a vast country like British West Africa, with its almost limitless wealth and resources, was of paramount importance as a civilizing factor. Indeed, it may rightly be held that currency, more than anything else, tends to the rapid development of the commerce and resources of any country just awakening to the benefits of civilization.

The introduction of a properly constituted Bank in West Africa had at once an immediate and striking effect. It began to broaden the basis of trade and, by providing financial assistance to the smaller European merchants, brought the trade of the country into the hands of the many instead of leaving it in the hands of the few. It also brought the natives to realize the benefits of a money currency compared with the old system of barter.

The most obvious and important advantage obtained by the natives of West Africa through the introduction of a money currency may here be briefly described :

In the years preceding the establishment of a bank, the natives from the interior of the Colonies were in the habit of bringing down

to the coast towns the raw products of the country (palm oil, palm kernels, rubber, ivory, gum, etc.) for the purpose of exchanging such with the European merchants. Payment for these products was made by the European houses principally by means of manufactured goods of all descriptions, rice, tobacco, spirits, brass rods and small copper rings known as manillas. It is obvious that this method of exchange could not prove of lasting benefit to the native, and there was naturally a limit to the demand for such commodities. It follows, therefore, that no particular advantage was to be gained by the natives by fostering and preserving the cultivation of the products of the country.

With the establishment of a standard money currency and the introduction of a bank, however, these obvious disadvantages rapidly disappeared: the natives were not slow to realize that money had a value far greater than any other form of exchange, providing as it did for the acquisition of wealth in a practical form.

The bank offered an inducement (in the shape of generous interest allowed on monies placed on deposit) for the encouragement of thrift, and as, at the present time, the natives have entrusted to the Bank some £800,000 sterling on current accounts and fixed deposits, it will at once be seen how the altered conditions have been understood and appreciated.

Through the medium of the Bank, British silver from the year 1894 to the present time has been poured into our West African possessions—over three and a half million pounds sterling having been shipped to West Africa during this period.

Just as the Bank of England is deputed to control the silver currency in Great Britain, so the control of the silver currency in British West Africa is very wisely left by the Royal Mint and the Colonial Office solely in the hands of the Bank of British West Africa. Only those versed in the difficulties connected with a purely silver currency can appreciate the onerous responsibilities of such a control. When the stocks of silver in one colony become excessive, the bank (at its own expense) moves the redundant coin to another colony where silver is required, and thus prevents the undue inflation of the currency which would otherwise arise through indiscriminate importation.

In practically all the British West African Colonies the year is divided into two seasons—a very rainy season and a dry season. The latter as a rule lasts from four to six months (from November to April), and it is during this period that the bulk of the produce of the country arrives at the coast towns from the interior for sale and shipment to Europe.

The Bank, at such times is called upon to supply from its various Coast branches enormous sums of money to the European mercantile houses in order to finance their purchases of produce. It will thus

be readily understood that it is imperative in the interests of the trade for the Bank to provide its various West African Branches with adequate resources for all possible demands, which have to be provided for apart altogether from the permanent cash reserves necessary at all the Bank's branches to meet the demands likely to be made on current and deposit accounts.

For this purpose, some months prior to the commencement of each produce season, the Bank at its various branches in West Africa gradually increases its normal reserves by accumulating British silver coin, and in addition large sums are shipped out annually from England by the Bank in anticipation of the trade requirements.

This part of the banking business of West Africa alone requires the most careful and intelligent consideration, and it is interesting to note that, at no time in the history of the Bank in West Africa, has it failed to supply in full the demands of the community for silver.

From the establishment of the first branch in West Africa at Lagos, the Bank of British West Africa rapidly opened other branches in the Gold Coast, Sierra Leone and Gambia Colonies, and at the present time this Bank has branches and agencies at every town of importance on the Coast Line and in the interior throughout the whole of British West Africa.

It would be impossible for even those who are experts in banking conditions in Great Britain to realise the difficulties and anxieties encountered in conducting a great banking business in West Africa. Special knowledge (born gradually of an intimate acquaintance with the conditions of the country and the habits of the natives) is an absolute essential for success; and an important factor in the success which the Bank of British West Africa has attained, is that all its senior officials, both at home and abroad, have been in the service of the Bank from its inception.

It is impossible adequately to describe in detail within the limits of a short article on West African Banking the benefits which have accrued to the West African possessions of the Crown by the introduction of a money currency and banking facilities, but they may be very briefly summarized as follows:—

(a) The abolition of the barter system, under which the commercial possibilities of a country cannot develop.

(b) The substitution of a money currency, through which the natives have learned the value of money and the advantages of thrift.

(c) The expansion of trade owing to the facilities the Bank offers in financing merchants (1) in England by advances on their outward shipments of merchandize, and (2) in Africa by advances against the homeward shipments of the produce of the country.

(d) The advantages gained by the Colonial Governments (1) through the bank assuming the onerous duty of controlling the silver currency; and (2) in the immense saving in expenditure effected in the Treasury Departments owing to the Bank taking charge of the revenue of the Colonies, and undertaking the transmission of Government funds to and from London.

Among the most remarkable instances of the commercial development of West Africa are the birth of the Cocoa industry on the Gold Coast, and the commencement of cotton growing in Nigeria. The unprecedented increase in the export of cocoa, and the steady growth in the output of cotton, have only been rendered possible by the banking facilities now obtainable in West Africa; and the more important European houses engaged in the West African trade are now the first to bear testimony to this.

The following statistics (kindly provided by the courtesy of Mr. A. H. Milne of the Liverpool Chamber of Commerce) are a remarkable proof of the wonderful increase in the principal imports and exports of the West African Colonies where the Bank has established branches. The figures given date in each case from the establishment of the Bank in the respective Colonies, and show, for comparison, the corresponding figures taken from the latest available returns.

1900	... ..	27,280
1908	... ..	540,821

These figures are the most eloquent testimony to the benefits which have accrued to the West African Colonies by the introduction of banking facilities into West Africa.

ROY WILSON.

P.S.—Since this article was written the Bank of British West Africa has sustained a severe loss through the removal, by death, of Sir Alfred Jones, K.C.M.G., the Founder and Chairman of the Bank

The Institution remains a monument, among many others, to his foresight and ability in promoting large measures for the benefit of the trade of the Empire.

R. W.

## REVIEWS AND NOTICES.

**The Legislation of the Empire**, being a survey of the legislative enactments of the British Dominions from 1898 to 1907. Edited, under the direction of the Society of Comparative Legislation, by C. G. A. BEDWELL, with a preface by the Rt. Hon. the EARL OF ROSEBERY and an introduction by Sir JOHN MACDONELL (4 Vols. : *Messrs. Butterworth & Co.* ; 2 Guineas).

FOR the purposes of this survey it has been necessary to examine more than eighteen thousand Acts, and in his suggestive preface the Earl of Rosebery views this vast output with some feeling of apprehension. "We cannot," he remarks, "shut out from ourselves the prospect that increasingly the Legislation will endeavour to raise and fortify the new structure of society, somewhat empirically, by means of legislation. Now, I watch this process with some vigilance and more anxiety, because I belong to that small school which does not believe that Law, in the long run, can greatly ameliorate humanity. I am not sure that I do not incline to that small heresy (if it be a heresy) that the State is most fortunate which achieves its own development by the character and individual efforts of its own citizens, and with as little support and guidance as possible from legislation. At any rate, certain I am that the progress of the State which is enabled to develop itself will be more sure and abundant than that of the State which rests on legislative measures for the achievement of its destiny." These remarks raise an interesting question, and an amplification of them with some reference to individual cases would have been welcome. No doubt the best asset of a state is the good qualities of its citizens. But, in the first place, there are imperfections in the best communities, and, in the second,

great energies and activities constantly create new fields for organisation, and the additions to the statute book are largely the reflections of strong individual movements. A general review of the recent legislation of the Empire shows that the chief effort which is being made all round is to deal with pauperism, poverty, crime, disease, vice and ignorance. There is, of course, room for doubt as to the remedies for these evils, but it can hardly be said on the whole that the state in dealing with them is displacing private efforts, or is doing in one way what individual work would do in another. It is much nearer to the truth to say that in these cases the state has stepped in because individual efforts have failed and have been bound to fail, and that a far higher standard of efficiency may be set up and reached when the joint powers of the community are applied to the task than when each man is left to grope for himself. The function of law in such cases is not to suppress private work but to secure the success of whatever is good in it. For this end rules binding on all are necessary. It is obvious that individual efforts, unless they receive the sanction and support of the state in this way, would constantly be liable to be nullified by the stupidity or selfishness of some part of the community. The greatness of the volume of legislation is the result of progressive ideas, and until some final stage of perfection is within reach the legislative activity shown in such matters will be in direct correspondence with the march of thought.

In any case, it is clear that the whole Empire shows the same general trend in this matter. In the ten years covered by these volumes there were passed about 25,000 statutes. In this mass of legislation there is a striking degree of homogeneity. "It has the same aims and it generally adopts the same means. Almost all the Legislatures are making similar experiments, all making similar resolutions. I shall have to point out that the form of legislation is being 'standardised.' I may add that the same ethical level is being adopted. Thus there is unity in purpose, in spirit, and in form. The fact that for many parts of the Empire there is the same Common Law gives the legislation a similar character; much of it is intended to repair defects in that law, and to adapt it to modern circumstances; for much of it there is a common background or substratum. There is also much conscious and direct imitation of English models. Many of the Colonial Legislatures keep step, so to speak, with the English Parliament." (Introduction.)

There is abundant legislation against drink, disease, and betting, and—except in South Africa—for the protection of labour

by sanitary requirements, the maintenance of wages, the settlement of disputes, and the limitation of hours. Crime is being fought largely by indirect means. Prevention is aimed at rather than punishment, by such means as the segregation of the young and of first offenders. A large group of statutes provide for education, but it may be observed that there is very little reference to secondary education. Usually in these statutes there appears no trace of any religious difficulty, but an interesting settlement of the question has been made in the Orange River Colony, where a purely historical handbook is used in the schools (attendance at such times being optional), and dogmatic instruction may be given by any minister of religion after school hours.

The fourth volume of this work contains an analytical index to the subjects dealt with, so that a comparison of the provisions in different places may be easily made. The work has been thoroughly well done, and is highly creditable to the Society and its band of zealous workers.

---

**The Union of South Africa.** By the HON. R. H. BRAND. (Oxford; Clarendon Press. 6s. net.)

In this volume Mr. Brand gives an explanatory account of the provisions of the South Africa Act, 1909, the full text of which is printed in an Appendix. There is a very brief historical chapter and two chapters at the close are devoted to an attempt to forecast the future of politics in South Africa and of South Africa's relation to the rest of the Empire. But the treatment of these subjects is necessarily very slight, the author's object having been to describe the nature of the constitution itself, and to subordinate all other considerations to this description. As Secretary to the Transvaal delegates at the Convention, Mr. Brand had every opportunity of becoming familiar with the details of the measure as it gradually took shape, and his account of them is clear and easily intelligible. The book is intended for the general reader rather than for the expert student, and there is therefore no elaborate comparison with other constitutions or analysis of the origins of the various parts of the constitution. The student in search of these will naturally turn to "The Foundations of Union," recently published anonymously in South Africa. Mr. Brand tends, not unnaturally, in nearly all matters which formed the subject of dispute, to adopt the Transvaal point of view, and adherents of Cape Colony may find something to criticize on this score; but as a rule he is singularly free from any partisan bias.

The South Africa Act is remarkable for the absence of limitations on the power of Parliament to amend the constitution, and this feature hardly seems to us to receive adequate treatment in this volume. When several states agree to coalesce into a single unit, it is a common thing for the instrument of union to be regarded as having the nature of a treaty, unalterable except by consent of all the contracting parties. The existence of this sentiment is obvious in the case of the United States of America and the Commonwealth of Australia. It exists even in the case of the United Kingdom, as is shown whenever suggestions for reducing the representation of Ireland in the House of Commons come up for discussion. But in South Africa the States which make up the Union have been singularly confiding, and no trace of the treaty notion appears in the constitution. Mr. Brand is very doubtful as to the prospects of the new provincial constitutions proving a success in practice, and he regards this part of the South Africa Act as a leap in the dark. It is at any rate a highly interesting experiment, for which there is, so far as we are aware, no exact precedent in any part of the British dominions, and it is a testimony to the originality of the framers of the constitution.

---

**The Cradle of New France.** By A. G. DOUGHTY, C.M.G.; Litt.D.  
Dominion Archivist (*Longmans, Green & Co.*, 6s. net.)

Quebec, as Mr. Doughty observes, is unique. The glory of its position is without rival. It is rich in memorials of the past, and singularly interesting as typifying the union of two great nations wide apart in political and religious views. It is the birthplace of North American Literature, for here were penned the writings of Cartier and Champlain.

The early years of the French settlement saw a great amount of hardship, and it is curious to read that at one time it was almost starving, a handful of pease or a few roots being doled out daily. The explanation was that most of the settlers still depended on France for the necessaries of life, preferring the lucrative fur trade to toilsome agriculture. They kept up, however, a vigorous social life, and the gaieties of the Canadian winter made a good start at Quebec. From the beginning they established their reputation for having large families. The paternal government of France assisted the process by sending out cargoes of girls of the poorer class, and no time was lost on their arrival.

“ Marriage in those days was a matter not of inclination but of duty. A girl must be wed when she was fifteen, and a boy before he had reached the age of twenty. For the bachelor there was no sympathy; single blessedness was not popular in high places.

“ Before the arrival of the ships with marriageable damsels, all bachelors were warned that their hunting privileges would be cancelled unless they chose a partner for life within fifteen days after the arrival of the vessels. This somewhat indecorous method of disposing of the girls left scanty time for courtship, and the most presentable youth had the best chance of securing the most attractive girl for his bride. The laggard, no doubt, met with his desert. There appears, however, to have been quite a scrimmage amongst the bachelors to obtain a point of vantage.

“ The king manifested a lively interest in the increase of the population. Writing to the Intendant upon one occasion he predicted that there would be eleven hundred births in Canada during the next year.”

The union of the two nations after the war was quickly accomplished. General Carleton, sixteen years after he had fought under Wolfe, led both English and French against the Americans under Arnold. “ Two great factors, the clergy and the *seigneurs*, assured the loyalty of the French to England. It was the aim of the clerics after the Cession to render their flocks obedient to the new order and to accept the accomplished fact recognised by France and confirmed by the Treaty of Paris. The tenets of their religion and their traditional training led them to exact submission to constituted authority. The most influential class after the clergy were the *seigneurs*. To them it was a simple matter to transfer their allegiance from one sovereign to another. With the nobles of old France, ideas of king and country were associated, and often the monarch overshadowed every other consideration. Strong monarchical convictions therefore inclined them towards the English king, and Papineau had said in 1820 that the change of allegiance caused no regret, considering the superiority of the character of George III. over that of Louis XV.”

Mr. Doughty's book is brightly written, and with an appreciation of the incidents which show character. It contains a detailed account of the buildings and monuments of Quebec and a number of interesting illustrations.

**Another View of Cyprus.**

In our April number we noticed Mr. Stewart's volume entitled "My Experiences of the Island of Cyprus," which gave a very pessimistic account of the climate, scenery and health conditions of the island. Mr. Anton Bertram, Judge of the Supreme Court of Cyprus, has an article in the October number of "Travel and Exploration," written largely by way of protest against Mr. Stewart's conclusions. Mr. Bertram recalls the innumerable literary and historical associations of the island, the praise which it won from Euripides and Virgil, the legends which connected Aphrodite and Adonis, Teucer and Ascanius, with it, the visit of Paul and Barnabas, the marriage of Richard Cœur de Lion, the tragedy of Othello; and he sets himself to ask whether Cyprus is an unworthy theatre for so rich a variety of drama, in the course of which the destinies of the island have been controlled in turn by the Phœnicians, the Egyptians, the Persians, the Greeks, the Ptolemies, the Romans, the Byzantines, the Saracens, the English, the Lusignans, the Templars, the Genoese, the Venetians, the Turks, and now lastly by the English again. Mr. Bertram has a very complete and thorough knowledge of the scenery of the island, and his description is likely to awake in many readers a longing to visit it. He admits that Cyprus has "tracts which are dreary beyond description"; but he claims for it also "beauties that ravish the soul." We quote a short description of the Kyrenia coast, but we commend the whole of Mr. Bertram's article to our readers:—

"When I approach the Kyrenia coast I am in danger of becoming rhapsodic. But the Kyrenia coast is *sui generis*—a thing apart. Speaking with all possible self-restraint, I say that I know no more enchanting spectacle than that long line of graceful mountain tops that stretches from beyond the romantic castle of St. Hilarion away to the distant Carpas. Far beneath you, as you cross the pass from Nikosia, lies the blue Mediterranean, and across it you see the snow-capped mountains of Asia Minor. The spring flowers here are more lavish than anywhere in Cyprus. The hill-sides are almost a carpet of cyclamen. As you descend to Kyrenia, you feel that this side of Cyprus possesses what the rest lacks. There is a certain austerity about the rest of Cyprus. Here you have the richness of Italy. Indeed, as you walk through the streets of Kyrenia and see the gardens, the flowering trees, the steep descending steps, you might think yourself in some Italian sea-side town. . . . It is much as you feel when you descend from the Engadine to the Lake of Como. Some day, the world—the English and American world, that throngs the hotels and bazaars of Cairo and makes excursions into the Egyptian desert—

will discover the Kyrenia coast. When Cairo becomes too hot to be bearable, Kyrenia is at its best. To my mind the change from the Cairo season to the cyclamen and anemones of Kyrenia must be much like coming from a ball-room into a summer garden at sunrise."

---

**Agriculture in the Tropics.** By J. C. WILLIS, M.A., Sc.D., Director of the Royal Botanic Gardens, Ceylon, &c., &c., &c. (*Cambridge University Press.* 7s. 6d. net).

Under the above title Dr. Willis has written a treatise which should prove of exceptional interest, in that it deals with tropical agriculture in a broad philosophic spirit, treating the subject from the point of view of the administrator, the student, the experiment station worker, and also of the investor, for whose advice and guidance the book is mainly written. The needs of the planter engaged in producing any specific crop have not been catered for; he, in many instances, has access to works of reference treating more or less exhaustively of the industry with which he is concerned. It does not follow, however, that this work is without interest for the planter, but it is mainly concerned with general matters of policy and development.

It is significant that modern colonial administration is steadily assimilating the idea that the correct handling of agricultural problems constitutes one of the first essentials of government, that the care for and development of the agricultural resources of our tropical possessions must be a function of government, and cannot be left entirely to industrial enterprise, and that the action of a wise government in aiding, guiding, and urging forward agricultural enterprises is the safest line of policy to ensure the maximum of development with the minimum loss of energy.

To those who are interested in this side of the question, Dr. Willis's book will form most useful and instructive reading.

In some parts of the book the aspect of the eastern tropics, and particularly of Ceylon, are obviously very present in the writer's mind. This is natural from the close association of Dr. Willis with the agriculture of these regions, and while perhaps his perspective may not be quite so accurate when he treats of some other places, it enables him to give us many faithful pictures of tropical problems under aspects not usually presented in agricultural works.

The views put forward relating to the interdependence of Land, Labour, and Capital, and the influence of each in the development

of successful tropical enterprises, may afford European readers food for thought, and they may be led to see that something more than a little capital and a determination to work hard are essential to the success of the young man who seeks to establish himself in a tropical colony. The habits of the agricultural labourer and the effect that they may have upon enterprises, as well as many similar matters, are tersely indicated in a manner calculated to throw light on some successes as well as on some failures.

The manner in which each individual crop, or group of crops, is treated is rather that of the general observer who wishes to study or indicate the broad lines of improvement or development which may be looked for or aimed at in each instance. The general nature and prospects of the crop are indicated, the methods employed are briefly sketched, and there is usually an interesting note or discussion hinting at the useful lines of policy which should be followed in order to attain greater success or to ensure stability. All this is useful and stimulating, for, while the individual planter may often be alert as regards the details of his own particular culture, he may lose sight of broad general principles, or of wants happening at a distance which may profoundly modify his chances of success.

The information given and the views expressed in Part III., dealing with the general aspect of agricultural affairs in the tropics, form interesting and instructive reading, while Part IV., which treats of Agricultural Organisation and Policy, should be carefully studied by all interested in the government of our tropical possessions, by all who are connected with botanic or experiment station work, and by all who are commercially interested in tropical agricultural enterprises.

The fact that Dr. Willis can state with conviction that without the aid of the Botanic Gardens Ceylon would have remained a small and unimportant "native possession," is a highly significant fact, the full meaning of which we trust may be recognised.

FRANCIS WATTS.

---

**Wanderings among South Sea Savages.** By H. WILFRID WALKER. (*Witherby & Co.*, 7s. 6d.)

There is still much of the primitive and romantic in the South Seas, though it is fast changing, and the enterprising traveller can find the old customs and ideas, kept in check as they may be by the new law. Thus the ex-cannibals of Fiji have not died out,

and still expatiate on the attractions of the habit. Mr. Walker heard a story by some of them of how they boiled the feet and boots of a white man for days, not knowing that they were separate, and that they did not like the taste of the boots. His narrative ranges over Fiji, the Philippines, Papua and Borneo, and every part of it shows the facility with which he got into intimate acquaintance with the natives. The account of the Dayaks of Borneo is particularly interesting.

---

**The Nandi, their Language and Folk-Lore.** By A. C. HOLLIS, with Introduction by Sir C. ELIOT (*Oxford Clarendon Press*).

This is a careful study of the customs and language of the inhabitants of the Nandi plateau, one of the most beautiful districts in the East Africa Protectorate. They have been a fighting tribe, and carried this so far as to attack the Uganda Railway, for which indiscretion they were placed in a reserve. The principal medicine man is the supreme chief, and the Nandi believe implicitly in his powers. The totem idea is well developed, and there are many curious customs interesting to anthropologists.

---

**Mosquito or Man? The Conquest of the Tropical World.**

By Sir RUBERT W. BOYCE, M.B.; F.R.S. (*John Murray*, 10s. 6d. net.)

In this volume Sir Rubert Boyce traces the history of the theory of insect-borne disease, and describes with considerable fulness the campaign which is being conducted against the mosquito. He supports the belief that the immunity of Barbados from malaria is due to the small fish known as "millions"; these have been tried elsewhere without success, but perhaps it is hardly fair to come to a conclusion from a comparatively small consignment. The book is excellently illustrated.

---

**The Recognition of Minerals.** By C. G. MOORE (*The Mining Journal*, 7s. 6d. net).

A man who finds himself stationed at some unexplored place can hardly have a more interesting hobby than prospecting for minerals, and there is always the chance that a valuable find may reward his labours. There is a story of a father who took his son to a certain scientific institution and enjoined upon the authorities

that all that he wanted them to teach the youngster was how to find gold "in paying quantities." This is no doubt a laudable aspiration, but the prospector may often miss chances if he looks only for gold. There are many comparatively rare metals, new uses for which are continually being found by modern industrial methods, and the prospector should therefore be prepared for whatever he comes across. Mr. Moore, who has been resident chemist to the Ashanti Goldfields Corporation, catalogues all the minerals of any value, explaining their characteristics and showing how they can be recognised by simple tests. The descriptions are easily intelligible, and are exactly what are wanted by the amateur who cannot follow the assays of the professional chemist.

---

**Geology of the Cape** (13th Report of the Geological Commission, Cape Town).

During 1908 the work of the survey was carried on in the Divisions of Britstown, Prieska, Victoria West, Carnarvon and Hay. Much new information was obtained about the peculiar rocks allied to the Kimberlite group occupying fissures and pipes in these districts.

---

**Ferro-Concrete.**

The monthly magazine "Ferro-Concrete" has been instituted to keep the many persons who are interested in the system abreast of current development. (2s. 6d. per annum, post free.)

---

Among recent Colonial publications may be mentioned a report on locusts and their destruction, by the Cape Government Entomologist; a report on the Forests of British East Africa, by Mr. D. E. Hutchins (Cd. 4723); and the proceedings of the South African Irrigation Congress (Capetown). A booklet on the erection and working of cotton gins may be commended to those who have to use these machines (Imperial Department of Agriculture for the West Indies: 4d.). The Barbados Commission's report on the Customs deals with many points of general interest as regards the collection of customs revenue and the want mainly of goods.

Among the Colonial Reports, that on the results of the mineral survey of Nyasaland (Cd. 4908), by Prof. W. Dunstan, includes an account of the coal areas near Lake Nyasa, which will be an asset of great value. The report on the cotton industry in Uganda

(Cd. 4910) explains why it became necessary to maintain the standard of quality by legislative provisions. Within a radius of 100 miles from the shores of Victoria Nyanza there are "more than a million able-bodied landowners eager to grow cotton, and at least 20,000 square miles of land eminently suitable for the production of that product."

In the account of agriculture and viticulture in South Africa (Cd. 4909), Lord Blyth discusses the various products and recommends the appointment of an Agricultural Advisory Committee for the whole Empire. The soils and climate of South Africa are, he considers, "all round equal, if not superior, for cultivation to those of almost any other part of the globe."

## BUSINESS NOTES.

### Motor Transport.

The annual report for 1908 of the Mechanical Transport Committee is full of interesting matter. The most important point for undeveloped countries is that the Hornsby chain track tractor has given satisfaction. This conclusion opens up new prospects for places where there are no roads or where horses cannot live. A high-speed car has been built for desert work in Egypt. The Hornsby car is built on two separate frames. The upper frame carries the six-cylinder engine, clutch, gear-box, etc., and is a standard 75-b.h.p. "Mercedes" pattern. The lower frame carries the chain tracks with their driving and guide wheels and axles. In a trial over dry soft sand, a speed of over 20 miles an hour was attained, with nine persons on board, and the running was smooth and remarkably free from undulation; a length of bearing of 9 feet was afforded by the chain tracks, the centre of the track having sunk to a depth of 2 inches. Considerable improvements have been made on the original design.

In the War Office competition for light tractors the prize was awarded to Messrs. Thornycroft, whose tractor was considered a very considerable advance on any hitherto tried.

The petrol specification has been revised to include a spirit of higher specific gravity (715 to 725), which is far cheaper than the lighter varieties. Under the worst possible conditions the engine can be started by injecting a few drops of a lighter spirit or by putting warm water in the cooling system. It should be borne in mind when special brands are asked for from the Colonies that the distillers of these makes do not always possess a bonding house at the most convenient port of shipment, and some expense and delay may be saved by ordering petrol to a specification.

The Committee have tried Elastes-filled tyres, but did not find them satisfactory. The Crown Agents have sent a car so fitted to Nigeria. "Miraculum" is not recommended, as being of no use in the case of large cuts or burst tyres. The Palmer tyre is recommended as being the best and cheapest, having about 50 per cent. longer life than the steel-studded.

---

### Cotton.

The output of cotton continues to increase in West and East Africa, and the British Cotton-growing Association has now produced a quantity representing about £2,000,000, at a cost of £125,000. The output, however, is very small compared with the American, and more money is greatly wanted by the Association to extend its field of enterprise. An application has been made to the Government for a grant towards the cost of the pioneer work, but it can hardly be urged in support of this that Lancashire has shown itself keenly concerned in the matter. The textile industry has not been in such a condition as to suggest that the public at large should contribute to help it, and if the county principally concerned does not care to subscribe substantially for the development of cotton-growing in our own possessions, there is not much of a case why anyone else should. It is to be hoped that the funds of the Association will increase, and in the meantime it is satisfactory to notice that excellent cotton can be grown in so many of the Colonies.

---

### Water Finder.

Our old friend the divining rod still commands a considerable following, and though recently a municipal auditor in this country refused to pass the expenditure for one on the ground that it was a pure waste of money, there is substantial evidence that there is something in the idea. The housemaid's practice of encouraging a fire to light by putting a poker in front of it was cited by Herbert Spencer as an example of civilised superstition, but it has lately been upheld on abstract scientific grounds, and possibly other like customs may be whitewashed in the same way. An automatic water finder has been brought out which is based on an undeniably scientific principle, which may be at the bottom of the many successes of the divining rod. Electrical earth currents exist in all parts of the world, and the density of such currents will naturally be greater when the strata are rendered conducting by water. It is claimed that if subterranean flowing water is present below the instrument, the magnetic needle provided will move, the strength of its swing depending on the volume of flowing

water below. A trial of the instrument has been made by the Transvaal Government, and the observer came to the conclusion that it will probably prove of value, though satisfactory results are not to be expected on days of excessive heat or when the ground is saturated after heavy rain.

The prices are £100 and £50, according to size.

---

### The Fibre Industry.

Various enterprises are springing up for the exploitation of this product in the West Indies and Africa, and there should be good openings for them if they are well managed. In a report on the sisal industry of the Turks and Caicos Islands, it has been stated that in the first year from 30 to 40 leaves can be taken off each plant, the number diminishing each subsequent year. From this it has been computed that in ten years a plant would yield 190 lbs. of leaves, which, at  $5\frac{1}{2}$  per cent. of dry fibre, would represent  $10\frac{1}{2}$  lbs. weight of fibre; taking this at an average price of 3d. per lb., each plant would yield 2s. 7 $\frac{1}{2}$ d. Much depends on the machine used. The great German firm of Krupp has taken this matter up and sent a representative to study the conditions in East Africa, and they are now turning out a machine which it is believed will extract all the fibre from the leaves, say at least 8 per cent. The price, however, is high; we understand it is £750, without the power. There are British-made machines on the market, which are constructed on good theoretical principles, but they have not established a reputation as adapted to the working conditions. It is to be hoped that the British manufacturer will not be left behind in this matter, as the business is sure to grow greatly.

---

### Filters.

Enquiries are occasionally made as to the best filtration system for public institutions. A series of enquiries on the subject has been recorded in the "Journal of Hygiene." Earthenware has from ancient times been recognised as a good filtering material, as it aerates water and retains matter, but ordinary filters do not prevent the passage of disease organisms. Experiments have showed that the Doulton white porcelain filter and the Pasteur Chamberland do not allow the direct transmission of contaminated matter, but do permit of indirect contamination by growth through the filter mass. This contamination was less in the Doulton than in the Chamberland filters, and on resterilisation the candles in the former again gave germ-free filtrates. As a material for pressure

filtration the Doulton porcelain preparation was pronounced to be at least the equal of the best materials on the market. But sterilisation should be carried out every three or four days.

The Berkefeld filter used to be considered an effective disease preventor, but in recent comparisons of the Doulton, Berkefeld, and Slack and Brownlow filters, it was found that the Doulton alone uniformly prevented the direct transmission of micro-organisms, the Berkefeld with one exception allowed transmission, and the Slack and Brownlow allowed transmission immediately.

The efficiency of a filter in this respect seems to depend on the porosity. The smaller the size of pore or grain the greater the efficiency. The microscopic comparisons show that the Doulton filter has the smallest grain.

---

### Motor Fire Escape for Melbourne.

Australia is well to the fore in the adoption of motor fire apparatus, and machines of this class are to be found at Sydney, Melbourne, Adelaide, and Brisbane. The two first-named cities have each given several repeat orders, and the Melbourne Fire Brigade has just received delivery of its fourth Merryweather petrol motor appliance. This comprises a powerful 55-h.p. motor chassis, carrying a 50-ft. fire escape, together with a capacious box for accommodating hose and usual gear for getting to work from street hydrants. Several firemen can be carried, and a speed of 25 to 30 miles an hour attained. The escape, which is of the "sliding carriage" pattern, can be detached from the vehicle in a few seconds when required for use. Solid rubber tyres are fitted to the wheels, those in the rear being of twin section.

---

### River Transport.

A scheme has been prepared by Messrs. G. Rennie & Co. for a generating tug working lighters provided with electrical motors. As soon as the cables were coupled up, the whole fleet would be ready to get under way, and as each unit is self-propelled and self-contained the man at the wheel would have control to direct his vessel round the bends. The system would have advantages on rivers where a considerable cargo can be taken up at a time. Some of the points given in favour of the scheme are that:—

“In the case of shallow draft tugs, it is well known that owing to the limited size of the propellor, and this also applies to screw in tunnel boats, a high number of revolutions has to be made in order to get the requisite power, and this is very undesirable for a high towing efficiency.

“Whereas in this system, owing to the power being split up into a number of propellers, the highest efficiency can be obtained from each propeller.

“It is also apparent that only the amount of electricity that is actually required need be generated, so that if the fleet is composed of only two barges, sufficient power will be generated for three motors only, one for the tug and two for the barges.

“Whereas in the ordinary tow boat, the machinery is generally working at its full power whether towing two or five barges or any other number.

“It is reasonable to suppose therefore that there will be a very considerable saving in the electrical unit system, and this is of the very greatest importance where the cost of fuel is a consideration.

“As regards dirigibility, it has already been pointed out that in navigating a river which is full of sand banks and shallows, it would be of the greatest convenience for such a vessel to be self-propelled, and to steer her own course.

“Everyone has seen the difficulty which a string of barges has in rounding a sharp bend in a river or in a canal, the tail barges usually swinging round and sometimes causing considerable damage to other craft or themselves.

“This difficulty is entirely overcome by the unit system, and the point is worth considering.

“With regard to the up-keep, we have every confidence in saying that there is no engine which gives less trouble than the modern electric light engine, which, being entirely enclosed and under forced lubrication throughout, requires very little attention.

“The same may be said of the modern electric motor, with which all modern factories are now equipped, and which run from year to year with the minimum of attention.

“It is therefore not necessary to have a skilled man of any sort on the lighters, and a native pilot could handle the boat with perfect ease.

“Other minor advantages, such as a brilliantly illuminated fleet at night with powerful lights to guide them, will save a considerable time in the transport of goods.

“In some cases the power boat may be put to special uses on arrival at its destination, for supplying power to electric cranes to unload the cargo, working sawmills, and other temporary machinery.

“The question of cost is naturally of great importance to the purchaser, but the outlay is not much greater than, say, a powerful stern wheel steamer and an equal number of barges, and we confidently anticipate that the extra cost of this system would very soon repay the owner.”

---

### Irrigation Notes.

Irrigation on a large scale has been attended with such striking results in many places that people are apt to conclude that it can be introduced with success on any land. This is far from being the case; the amount of land which is suitable for irrigation of this kind is comparatively small. It is essential that there should be a substantial depth of soil, and this generally excludes the uplands. Usually proper conditions are only met with in the alluvium of rivers. The sub-soil has also to be examined to see that it admits of drainage. It has sometimes happened that irrigation water has brought to the surface such excessive quantities of salt that it has been almost impossible to continue the cultivation of the land. It should therefore be ascertained whether the soil contains any deleterious brack salts, and for this purpose a sample from the surface is useless; a piece more than one foot deep should be taken.

The small holder who makes his own storage is usually content with an earthen bank to serve as the dam. In this case the excavation for the soil should be up-stream, so as to form additional storage. High earthen dams are dangerous, and for substantial storage cement is necessary, but up to a certain point lime is good enough, and silt-laden water in time forms a fairly effective packing on a gravel floor.

A substantial earthen bank dam should be made with the help of proper machinery. The appliances used in America are generally wheel scrapers and dump wagons; the filling of the latter is done by an elevated grader, and the machine is certainly very effective for loading soil. Usually the cost would be beyond the means of the farmer, and the only plan is for the Government to provide the plant, charging for the use of it, or for a contractor to undertake the work.

The need for irrigation and the mischiefs of erosion in South Africa are dealt with in a small book entitled “Utilisation of Flood Water,” published at Cape Town. The law of the Colony has stood in the way of improvements, and though an Act of 1906 has done great good, there is room for improvement, and a movement is going on for further reform. In all such cases it is old

rights to water that stand in the way of general schemes. The Gordian knot was cut in Italy by Count Cavour's government by decreeing all rivers public property, and modern Italy owes much of its prosperity to this strong legislation.

### American *v.* English Small Arms.

The Australian Commonwealth Government, having decided to set up their own small arms factory, invited tenders for machines, plant, and motive power on the 1st of January last year. The results were instructive, if not gratifying to British pride. The following tenders were received for machines capable of turning out 50 M.L.E. Mark III. rifles per day, or 15,000 a year:—

Bir. Small Arms Coy. ...	£150,231	...	Time, 2½ years.
Archdale and Coy., Birmingham	100,438	...	" 3 "
Greenwood and Batley, Leeds	69,141	...	" 2 " less 5 weeks.
Pratt and Whitney, U.S.A. ...	68,144	...	" 1 year and 16 weeks (subsequently reduced to 1 year.)

These tenders were considered with great care, and it became clear that the great disparity was due to differences in ideas as to the best system of manufacture. The B.S.A. Co. considered that it was desirable to provide for separate machines for each operation, but the two lowest tenderers did not share this opinion. In May, after considerable telegraphic correspondence with Capt. M. Collins, the Commonwealth Government directed that an expert should be sent to America to visit and report upon Messrs. Pratt and Whitney's works. The expert returned satisfied that the machinery there could manufacture small arms more efficiently than any European, and could in many cases turn out double the work produced by English machinery. The firm stated that any pattern of rifle could be made and any change of pattern provided for by changing the fixtures. It was further urged that there was a considerable economy of labour by the use of their machines. The War Office were consulted, and gave an opinion in favour of the B.S.A. Co.'s tender, considering that American machinery was less durable than English and therefore more expensive. The expert, on the other hand, considered that this objection to American machinery was not applicable to Messrs. Pratt and Whitney, and that the War Office was not aware of recent developments in small arms machinery in America. The price of the War Office rifle was £4. 5s., while under Pratt and Whitney's scheme it would be £3. 9s. 1d., and it is not surprising, therefore, to learn that the tender of this firm was accepted.

## RAILWAY NOTES.

### Ceylon.

The gross receipts in 1908 were the highest recorded, and show a steady increase of prosperity. A large sum was expended in increasing the stability of the line against slips and washaways. The old passenger carriages are gradually being superseded by modern bogie stock, and of these increasing parts year by year are being made in the Colony. The new British standard 80-lb. rail and angle fish plate have been adopted in the low country broad-gauge sections in lieu of the old 72-lb. section. The increasing traffic is making it necessary to adopt a heavier type of engine, and, as generally happens, this brings up the prospect of having to strengthen the bridges. The Mannar Line will be a splendid running road, capable of fast time and fit for heavy engines. The suburban sea-coast railway, which carries many thousands in and out of Colombo daily over an ill-equipped single line, will be improved, and there is hope that the present barn-like structures will before long be replaced by decent stations. It need hardly be said that the carriage of rubber has increased, the tonnage being 183; in 1906 it was only 37; but this is a trifling matter for the railway, which looks chiefly to rice and tea.

---

### Mannar Railway.

The South Indian Railway authorities anticipate that they will complete the works on their side by the end of 1911.

**Gold Coast.**

The construction of the Accra—Akwapim Railway, which was commenced in January, 1908, has been carried on by the contractor uninterruptedly and with considerable energy, and the work has been done in a very creditable manner. It is anticipated that the line will reach Insuam (26 miles) by the end of March, and Mongoase (40) by the end of June.

The railhead of the Tarkwa-Prestca line was at 14 miles at the end of September, and will, it is expected, reach Prestca in April.

---

**Lagos.**

At the end of September the earthworks on the Ilorin-Jebba section were completed. There was no difficulty in obtaining labour, and 1,520 natives were employed. On the Jebba-Zungeru section the earthworks were completed for 49 miles; some difficulty was experienced in getting as much labour as was desired, but 3,237 natives were employed.

In spite of heavy rains, which caused much extra work, the concrete foundations for the trestle bridge on the Niger were completed, and the girderwork erected by the end of August.

### MEDICAL NOTES.

In Ceylon there was more malaria, small-pox, and enteric fever in 1908 than in 1907, and this was due mainly to want of rain. Sir Allan Perry, in his very clear report, observes that: "On all meteorological conditions, the rainfall has the greatest influence on the health of the people. Drought means hardship, agricultural pursuits are hindered, foods get scarce, wells run dry; with insufficient food and water low in the wells, bowel complaints are common; with insufficient rain the breeding places of mosquitoes are not washed out, mosquitoes therefore are left undisturbed, and a large amount of malaria is the result. The influence of the rainfall as a factor in increasing disease was very marked in Colombo during the year under review. There were long periods of drought, and the rainfall for the year was below the average. There was an unusual amount of sickness from serious disease in consequence. Similar meteorological conditions existed in 1906, which was a markedly unhealthy year. The incidence of malaria is determined by the monsoon rains. If the Island is roughly divided into western and eastern longitudinal halves, malarial fevers are commoner soon after the south-west monsoon in the western half of the Island, and after the north-east monsoon in the eastern half."

But when the insanitary conditions of many parts of the Island is considered, it is not surprising that there is a good deal of sickness. Sir A. Perry advocated the establishment of "mosquito brigades" to clear the breeding grounds, as in Sierra Leone, but only three local boards promised to take any serious action, and the others pleaded that no action was necessary. The Lunatic Asylum had the worst year in the history of the institution, but a picturesque feature is that in compliance with a general desire

expressed by the attendants, a religious ceremony was performed; whether this directly affected subsequent events is a question which the report discreetly leaves open, but "apart from belief in its efficacy as an instrument, its picturesqueness and solemnity impressed the imagination powerfully," and "did much to restore courage to the faint-hearted."

---

### Sleeping Sickness in Uganda.

The report of the Principal Medical Officer of the Uganda Protectorate on the work carried out at the Sleeping Sickness Camps shows that up to November 30th, 1908, a total of 5,081 cases had been received, some 2,000 remaining under treatment on the latter date. The tables accompanying the report show that "death continues to thin the ranks not merely of those admitted during the earliest months, but of such of these as on admission were still in the early stage of the disease. Many of those classed as 'improved' in former reports have now succumbed." The opinion is expressed that the camps have abundantly justified their existence. "Although purely from the point of view of the segregation of an infectious disease, and apart from the general preventive measures undertaken, I do not consider that the camps are or have been of any great value, they have been, on the other hand, very useful and necessary adjuncts to the general scheme for the prevention and stamping out of sleeping sickness. They have been of great value as asylums, where the sick who have been removed from dangerous areas have found refuge, and where very many persons who would otherwise have been subject to desertion, misery, and starvation have been housed, fed and medically cared for. They have also been, in my opinion, of considerable educational value. The fact that hundreds of sick have for long periods been collected in places from which *Glossina palpalis* is absent, and that the disease has in no case spread either to the attendants or in the neighbourhood, has materially assisted to impress on the natives (a task at first so difficult) the truth of that which they have been taught concerning the connection between the fly and the spread of sleeping sickness. They have thus been better able to understand the utility and *bonâ fides* of the action taken by Government to protect them from infection, and this better understanding has without doubt facilitated the carrying out of preventive measures which might otherwise have been regarded with much suspicion and resentment. An instance of this is the removal of the islanders to the mainland, which, though regarded until lately as impracticable, is now taking place with the full concurrence and assistance of the chiefs themselves." Unfortunately, the results of the attempts at curative treatment which

have been made in Uganda are far from encouraging, and the report quotes the opinion expressed by the chiefs that "though they think that many less people now have sleeping sickness, owing to the preventive measures which have been put in force, they do not yet know of any individual among their own people having recovered from the disease, with or without treatment." It is pointed out that laboratory experiments as to the influence of drugs on trypanosomes, whether *in vitro* or in the smaller animals, have proved less helpful than similar experiments in the case of many other diseases, the nature of the disease in man and in the animals experimented upon presenting wide divergences. The hopes entertained as to the curative results of atoxyl, anti-mony, and other drugs have been to a large extent disappointed, and "there is no longer question of the routine administration to all and sundry of a drug which, it was supposed, might probably effect a cure in a considerable number of cases, but rather of the careful testing of various remedies and methods of administration on series of selected cases, combined with accurate observation and tabulation of results continued over long periods." For this purpose the report recommends the establishment of a special central "investigation camp." The results of experience in the treatment of the disease by atoxyl are summed up as follows:—

"1. The improvement which occurs in many cases has not been maintained in the great majority of them.

"2. The prolongation of life which results has been of no benefit to the community, and of at least doubtful benefit to the patients themselves.

"3. Where the measures taken for preventing contact of the sick with the fly are practically complete, as in the Victoria Nyanza epidemic area, the diminution of infectivity produced by atoxyl treatment is of little value.

"4. The number of early cases which have maintained their improvement has steadily decreased, and the number of persons likely to be permanently cured is now inconsiderable.

"5. The results obtained from atoxyl and mercury do not at present seem any more likely to be permanent than those obtained from atoxyl alone.

"6. Increased experience in the use of organic arsenical remedies, combined with their practically constant supply in a chemically-pure condition, has not up to the present brought about any corresponding rate of improvement in statistics.

"7. It remains true that better results have been obtained from organic arsenic, alone or combined with other drugs, than from any other method."

The detailed statistical information embodied in the report affords terrible evidence of the ravages of the disease, and it is clear that Sleeping Sickness, like cancer, has up to the present baffled all the efforts of medical science. In each case hope for the future depends upon the ultimate success of scientific investigation, and the great concentration on the task of trained intellects and devoted labour forbids any suggestion of despair.

---

Doctor Bagshawe, the Director of the Sleeping Sickness Bureau, read at a meeting of the Society of Tropical Medicine and Hygiene a paper which gives a useful summary of recent advances in Our Knowledge of Sleeping Sickness. It has been reprinted, in pamphlet form, from the Transactions of the Society. The Sleeping Sickness Bureau has issued its eleventh Bulletin, and the wide recognition of the value of its work is shown by the unexpectedly large demand for its publications.

---

### The Compulsory Isolation of Apparently Healthy Persons.

Of recent medical developments nothing has mystified more completely the man in the street than the discovery that persons in apparently good health are capable of carrying infectious germs for an indefinite period and distributing them among their friends and neighbours. These "Carriers," as they are called amongst doctors, are obviously a danger to the community, and every effort is being made in hospitals and laboratories to find some effective means of driving the objectionable bacteria from the systems of afflicted persons.

The recent action of Sir William Collins in drawing the attention of Parliament to the detention of five soldiers at Millbank Military Hospital at once interested the general public in a matter that has hitherto been confined to professional circles. These soldiers, as the result of close observation by army surgeons, were strongly suspected of harbouring and excreting the bacillus of typhoid. One of them in particular had been responsible for the outbreak of several cases in his own regiment, and other cases occurred from time to time in units which happened to be quartered in his neighbourhood. All five of the soldiers referred to, as Mr. Haldane was careful to inform the House of Commons, exhibited no signs of ill-health beyond the excretion of the bacilli. Mr. Haldane admitted that so far no cure had been effected by the use of vaccines at Millbank, though persisted in for many weeks, and he added that cases had been recorded in which the bacilli were excreted by typhoid patients two years after they had been discharged from hospital as "cured."

Obviously no one who values his liberty would wish to be confined indefinitely in hospital, especially when enjoying apparently robust health, and the solution of the "carrier" trouble clearly affects the interests of every citizen. Early in 1908 the then Medical Superintendent of the Monsall Fever Hospital at Manchester—probably the largest institution of its kind in this country—contributed to the medical journals a note on the internal treatment of typhoid fever on antiseptic lines. He used medical izal oil with remarkable results, inasmuch as he found that when the drug was administered for a sufficiently long period, the bacilli of the coli-typhoid group usually disappeared, and the patients were discharged free from any suspicion of being "carriers." During the first year that this internal antiseptic treatment was introduced at the Monsall Hospital the cases of mortality from enteric fever was the lowest on record for that institution. It will not unlikely prove that the remedy for chronic "carriers" will be found in the internal administration of antiseptics such as medical izal oil—a method of treatment now being extensively used in fever hospitals at home and abroad.

---

In the Trinidad Medical Report for 1908-9 the Surgeon-General comments on the fact that the vigorous and effective measures taken to combat malaria and other tropical diseases in the Island have scarcely received adequate recognition in some quarters, and that there has been a tendency to brand Trinidad with an undeserved reputation for unhealthiness and indifference to sanitation. He draws attention to the very efficient manner in which an outbreak of bubonic plague was dealt with in 1908, nineteen cases in all being notified during 1909. Three isolated cases of yellow fever were notified during the year under report. Vigorous measures were taken to reduce the numbers of *Stegomyia* mosquitoes.

---

We have received from the Liverpool School of Tropical Medicine Vol. III., No. 1, of *Annals of Tropical Medicine and Parasitology*. This number, which contains 256 pages, is entirely taken up with the report of the Liverpool School's Blackwater Fever Expedition to Nyasaland in the years 1907 to 1909. The authors are Dr. J. O. Wakelin Barratt and Dr. Warrington Yorke.

---

Volume III., No. 2, of *Annals of Tropical Medicine and Parasitology* contains three important reports by Doctors Kinghorn and Montgomery (the members of the Liverpool School's Expedition to the Zambesi in 1907-9), dealing with Trypanosomiasis in men and in animals in Nyasaland and North-Eastern Rhodesia.

Volume III., No. 3, contains articles on Sanitary Measures and Malaria Epidemics in Athens, on a form of enlargement of the spleen, accompanied by cirrhosis of the liver, endemic in Egypt, and on Biochemical and Therapeutical Studies on Trypanosomiasis (by Doctors Breinl and Nierenstein).

Volume III., No. 4, contains instalments of the extremely valuable reports of the Liverpool School's Expedition to Jamaica in 1908-9. Doctor Newstead deals with Medical and Economic Entomology, and Doctor Prout, C.M.G., with Malaria.

## COLONIAL STAMPS.

Readers of these notes will probably have noticed an apparent revival of copper-plate printing recently among Colonial stamps. There is no doubt that for issues of between 100,000 and 800,000 stamps it is much more economical than the surface process, both the plates and printing being cheaper where a special design is adopted, and at least equally cheap as the Universal Key-plate stamps. The only serious objection to such stamps is that they are unsuitable for use in collection of Revenue unless the cancellation can only legally be made with proper cancelling ink. The process is also unsuitable for stamps of considerable value, because they are easier to clean, or for those printed in large numbers, because large numbers can be more cheaply printed by the surface process in more than one colour, as after the first printing the sheets must be dried and re-wetted for reception of the second colour, which almost doubles the cost of printing.

Several Colonies which use copper-plate stamps have decided to adopt the new colour scheme. It is obvious that this cannot be done to the full extent for values to which two colours are appropriated on the scheme, but the following scheme has been drawn up so as to include the leading features of each value. We name only the values in which the scheme could not be literally followed:—

<i>Valuc.</i>	<i>Colour of Ink.</i>	<i>Colour of Paper.</i>
3d. ....	Brown	Yellow.
4d. ....	Red	Yellow.
4½d. ....	Orange	White.
5d. ....	Sage Green	White.
2/- ....	Purple	Blue.
2/6 ....	Red	Blue.
3/- ....	Violet	White.
5/- ....	Green	Yellow.
10/- ....	Red	Green.
£1 ....	Black	Red.

It will be observed that there are two cases in which the colour scheme is entirely departed from. In one of these, however (the 3d. value), the difference is more apparent than real, as the brown ink on the yellow paper produces much more nearly than purple the same effect as that given by the surface printed 3d. stamp. The 4½d. stamp is in orange, because it is a value which has hitherto been seen only in one issue of copper-plate stamps, and there is no instance of a 1½d. stamp in this method of printing.

---

**BRITISH HONDURAS.**—1 cent stamps have been supplied on unsurfaced paper.

---

**BRITISH SOLOMON ISLANDS PROTECTORATE.**—Three new values have now been issued in addition to those recorded in our issue of July, 1908. These are 2s., 2s. 6d., and 5s. The colours adopted are those described above.

---

**FIJI.**—1s. postage and revenue stamps in the new colours have been supplied.

---

**HONG KONG.**—\$2 stamps have been supplied with black border and carmine centre on surfaced paper. A new 5 cents receipt stamp of a small size has been sent out, and it is intended to print no more 5 cents postage stamps, the use of which will be discontinued as soon as the present supply is exhausted.

---

**MALTA.**—The supply of the ½d. and 1d. stamps referred to in our last issue should have been recorded some time ago. The difference between the current ½d. stamp and that previously in use lies in the character of the ink used and the consequent use of unsurfaced paper for the current stamp. The ½d. stamp is now printed at one operation, but this produces little, if any, difference in its appearance.

---

**SIERRA LEONE.**—1½d. stamps have been supplied in the new colour.

---

**STRAITS SETTLEMENTS.**—The supply of \$100 stamps was recorded in error in our last number. The next supply will be printed in the colours stated in our issue for January last, and

will be of a large size, but none have yet been ordered. 50 cents and \$500 stamps, the latter a new value (see April number), and the former in the new colours, have been supplied.

---

**MELVILLE STAMP BOOKS.**—A Melville Stamp Book (6d.) gives a surprisingly full account of Papua, which, owing to constitutional changes, is exceptionally interesting to philatelists. Another issue deals with Tonga, which also has had a varied history in this respect since 1886.

**RECENT TRANSFERS AND PROMOTIONS  
MADE BY THE SECRETARY OF STATE.**

- Lieutenant-Colonel C. R. M. O'BRIEN, C.M.G. (late Deputy Commissioner, Transvaal Town Police), Colonial Secretary, Gambia.
- Mr. F. C. WELLS DURRANT (late Stipendiary Magistrate, St. Lucia), Attorney General, Bahamas.
- Mr. T. S. SIDNEY (formerly District Commissioner, Lagos), Attorney General, Leeward Islands.
- Mr. R. E. NOBLE (late Magistrate, East Africa Protectorate), Legal Assistant, St. Vincent.
- Mr. E. B. REECE (Chief Railway Accountant, Gold Coast), Treasurer, Gold Coast.
- Mr. S. B. GOSLING (Assistant Postmaster-General, East Africa Protectorate), Assistant Postmaster-General, Gold Coast.
- Major G. C. BAYLY (Local Commandant of Police, Cyprus), Commissioner of Papho, Cyprus.
- Mr. F. H. HAMILTON (retrenched from the Transvaal Civil Service), Senior Assistant Treasurer, Sierra Leone.
- Mr. S. F. STOKES (retrenched from the Transvaal Civil Service), District Engineer, Gold Coast.
- Mr. J. F. BLAKELEY (First Class Clerk, Treasury and Customs Department, British Honduras), Supervisor of Customs (Second Grade), Southern Nigeria.
- Mr. J. DALTON (Chief Warder, St. Catherine's District Prison, Jamaica), Keeper of Suva Gaol, Fiji.

- Mr. C. H. C. ADAMS (late Sub-Inspector, Cape Mounted Police), Assistant Commissioner of Police, Gold Coast.
- Mr. H. AULIFF (late Assistant Accountant, Public Works Department, Orange River Colony), Assistant Chief Clerk and Accountant, Public Works Department, Gold Coast.
- Dr. R. P. COCKIN (late Medical Officer, West African Medical Staff), District Medical Officer, Cyprus.
- Mr. A. GARDNER (late Government Schoolmaster, Straits Settlements), Headmaster of Primary School, Coomassie, Gold Coast.
- Mr. C. H. HART-DAVIS (District Commissioner, Gold Coast), Secretary to High Commissioner for the Western Pacific.
- Colonel COLIN HARDING, C.M.G. (formerly Commandant, Barotse Native Police, North Western Rhodesia), District Commissioner, Gold Coast.
- Mr. J. J. KILLINGBECK (Assistant Postmaster-General, Northern Nigeria), Assistant Postmaster-General, East Africa Protectorate.

## OFFICIALS ON LEAVE OF ABSENCE IN THIS COUNTRY WITH DATE OF EXPIRATION OF LEAVE.

—

This List is compiled from the Leave Certificates sent to the Crown Agents for the Colonies. The Editors will be glad to receive notice of any other cases of Colonial Officials on Long Leave.

EDITORIAL NOTES.

THE London season this year will have a special attraction for overseas visitors in the Festival of Empire, the chief events of which are to be held at the Crystal Palace from 24th May to 16th July. The principal feature is a great series of London Pageants, which will be presented twice a week, alternately every afternoon and evening. The house, 81, Piccadilly, has been generously lent to the Council by Mr. Burdett-Coutts, M.P., for the purpose of reception. There can be no doubt of the stimulating effect of the appeal to the eye which is afforded by well-devised pageants, and on this occasion it is certain that under the able direction of Mr. Frank Lascelles the spectacle will be an excellent one, and the *mise en scène*, as planned by Sir Aston Webb, will be superb. The public spirit which has led to the undertaking is in every way admirable, and will be widely appreciated. One notable result of it is that the railways promise to do the journey to the Palace in fifteen minutes.

The programmes and souvenirs are published by Messrs. Bemrose & Sons, 4, Snow Hill, London.

---

Reports from Canada indicate that the period of depression which set in in the autumn of 1907 has wholly passed away. Last  
Vol. III., No. 4.

season's agricultural results were very favourable, and their consequence was to bring a large amount of money into circulation. Favourable weather permitted navigation and outside operations in connection with railway construction to be continued until an unusually late date, and the year 1910 opened with exceptionally favourable prospects. The improvement during the past year is, as usual, reflected in the immigration returns, which show an increase of twenty-five per cent. over those for 1908, the quality of the immigrants also, it is said, showing a marked improvement. The general tendency of both wages and prices was in an upward direction. There was very great activity in railway construction, no less than 1,057 miles of new rails being laid in Western Canada alone. Altogether upwards of 4,000 miles of railway lines were under contract during the year, and the process of settlement in the new districts opened up went on with great rapidity.

---

In no country in the world have progress and prosperity been so closely bound up with the development of the means of communication as they have been in Canada. It was the construction of the Canadian Pacific Railway which first gave a sense of unity to the Dominion, and rendered it possible for British Columbia and Nova Scotia to feel themselves united by the bonds of a common nationality. In more recent years every fresh railway line constructed has served to open up new tracts of territory, to pour a flood of fresh settlers on the land, and to add to the great area of wheat cultivation. Canada is at present engaged on the construction of the National Trans-continental Railway, which will duplicate the line of communication between the Atlantic and the Pacific; and she has proclaimed her intention of proceeding at an early date with the construction of the Hudson's Bay Railway, which will open up an entirely new route of transit to Europe. But these projects, gigantic as they are, by no means exhaust the possibilities of the future. Last February an interesting debate took place in the Canadian House of Commons on the subject of the Georgian Bay Canal scheme. Mr. Pugsley and Mr. Fielding, who spoke for the Dominion Government, both professed themselves as strong supporters of the proposal, though the latter, in his capacity as Minister of Finance, felt bound to utter a word of caution as to the capital commitments of the Dominion, and was unable to give any definite promise that the scheme would be put in hand at an early date. But a proposal so strongly supported is not likely to remain a mere project for an indefinite period, and some particulars of the work contemplated will be of general interest.

---

The scheme is essentially one of river and lake canalization. It proposes to utilise natural waterways, which fortunately exist in an

almost continuous line from Georgian Bay, the north-eastern arm of Lake Huron to Montreal, the most important and the furthest inland of Canada's ocean ports. The line of the proposed canal would supply the most direct and shortest route from Lake Superior to the sea, and it is reasonable to suppose that it would become the natural outlet for east-borne freight from the west, including probably some of the Western States, as well as the "prairie provinces" of the Dominion. The total length of the proposed canal would be 440 miles, of which from 410 to 420 would follow the line of existing natural waterways. The aggregate length of purely artificial waterways would be no more than 28 miles, while over an additional 80 miles dredging or excavation would be requisite to procure the proposed minimum width of 300 feet and minimum depth of 22 feet. The total rise from Montreal to the summit would be 650 feet, and it is suggested that this should be overcome by 23 locks, ranging from 5 to 50 feet in lift, while four locks from 21 to 29 feet in lift would be required for the descent of 98 feet from the summit to Georgian Bay. Ample water storage is available, and it would be possible so to control the spring floods in the river reaches traversed as to obviate all risk of overflow, and give a maximum current in the canal, under extreme conditions, of three miles an hour. A minimum length of 650 feet and a minimum width of 63 feet is proposed for the locks, which would be equipped with double pairs of upper and lower gates. The total cost of the scheme is put at \$100,000,000. The time which would be occupied in transit by a vessel with a maximum speed of 12 miles per hour is estimated at 70 hours, and the season of navigation would average 210 days, from May to November. It will be realised that the scheme prepared is one of the largest ever attempted, but it is undoubtedly within the resources of the Dominion, and sooner or later it will be carried into effect. It is estimated that a "barge canal" with a depth of 14 feet could be constructed along the same route for a sum of from \$30,000,000 to \$40,000,000; but as the bulk of the navigation on the Great Lakes is effected by vessels drawing from 15 to 20 feet of water, and having a carrying capacity of from 5 to 13,000 tons, the adoption of this less ambitious scheme would involve breaking bulk twice, and would merely supply the Dominion with a duplicate of the 14 foot waterway from the Great Lakes to the Atlantic, which it already possesses. In these circumstances the costlier project would probably prove in the end to be the more profitable.

---

The commercial agreement recently concluded between Canada and Germany seem to have given rise to a certain amount of misunderstanding in the English press, and a short statement of the events which led up to it may be of service to our readers. Prior to

1898 the tariff relations between Canada and Germany were regulated by the Anglo-German treaty of 1865. This treaty contained no specific reference to Canada or to the British North America Provinces as then constituted ; but it applied to the whole Empire. The provisions of the treaty were materially different from those which are usually found in British treaties with foreign countries. Many of the old British treaties, not specifically relating to Canada, but applicable to the Empire at large, contain what are known as most favoured nation clauses. The effect of such clauses is that the British Government guarantees to the contracting nation the most favourable commercial advantages that may be granted to any other foreign country. The provisions of the treaty with Germany were much broader. The treaty provided that no other or higher duties should be levied in the British colonies on the products of Germany than on the products of the United Kingdom. This treaty and another of similar character were long regarded as objectionable, from a colonial point of view, as being an obstacle to freedom of commercial relations between the mother country and the outlying portions of the Empire. Representations from the colonies against the continuance of these treaties were made on several occasions. After the granting of a preferential tariff to Great Britain by Canada in 1897 the British Government denounced these treaties, and they were terminated on the first day of August, 1898. After that date German goods were entitled to admission into Canada under the General Tariff. Germany resented this state of affairs, and penalized Canada by subjecting Canadian products to the higher duties of the German tariff instead of the Conventional Tariff duties which had previously applied. Steps were taken by the Canadian Government to remonstrate against what was deemed to be an injustice to Canada. It was pointed out that the tariff relations between the United Kingdom and the colonies were matters of domestic concern with which no foreign Government could reasonably interfere ; that Germany should not claim the same privileges as were granted by the Dominion to the mother land ; and that Canada was granting to Germany the same terms as were granted to other foreign countries. Germany, however, refused to accept this reasoning and continued to impose the penalizing duties on Canadian products. After protracted and unsuccessful efforts to induce the German authorities to withdraw their demand for the same treatment as was accorded Great Britain, it was deemed necessary to apply to the products of Germany the surtax authorised by Section 7 of "The Customs Tariff, 1897," and accordingly regulations were made by an Order in Council of date the 28th day of November, 1903, subjecting articles, the produce or manufacture of Germany, to a surtax of one-third over and above the duties specified in the General Tariff. From that date up to the present time the products

of Germany imported into Canada have been subject to the duties of the General Tariff and of such surtax, and Canadian products imported into Germany have not received the benefits in any case of the Conventional Tariff rates. Under the agreement now concluded the special surtax hitherto levied by Canada upon German imports is suspended, and they are admitted under the term of the General Tariff, while in return Canada receives the benefits of the German Conventional Tariff upon a specified list of products. There is, it will be seen, no question of the granting to Germany of the special concessions made to France under the Franco-Canadian commercial convention, still less of the special advantages enjoyed by the United Kingdom by virtue of the Preferential Tariff.

---

On May 31st the South African Act of last year comes into operation, and the first Union Government must be formed. An influential body of opinion in South Africa has been in favour of a departure on this occasion from the old lines of political cleavage, and the formation in the first instance of a coalition government, or, as Dr. Jameson expresses it, a "government of the best men." This proposal is inspired by two principal motives, both of them deserving of all respect and sympathy: the desire to eliminate the last trace of racialism from politics, and the desire to concentrate the best efforts of the best minds of the country on the very complicated mass of constructive work which awaits the first Union Parliament. The proceedings of the South African Convention have shown how rich South Africa is in practical statesmanship, and how much can be accomplished by co-operation between the representatives of widely different schools of political thought. There is also a feeling that with the accomplishment of Union new problems have arisen, and that the old political parties in South Africa have become to some extent obsolete. But such an arrangement could only be carried out by general agreement, and of this there seems now to be but little prospect. The leaders of both parties in the Transvaal, and of the Progressives in the Cape are understood to favour the idea of coalition. But Mr. Merriman believes in party government upon the lines which are habitual in self-governing British communities. He considers it essential that there should be a strong government and a strong opposition, and that political problems should be dealt with in South Africa as they are elsewhere by methods which are the resultant of two opposing forces. Mr. Merriman apparently has on his side the leaders in the Orange River Colony, and so long as these two strong sections of opinion hold aloof no coalition seems possible. The question is clearly one for South Africa to decide for herself, but the discussion upon it has been followed with the closest interest at home. In any case the work of the future government will be

simplified by the return of prosperity, of which there are now abundant indications in South Africa, and the visit of the Prince and Princess of Wales, which has been definitely decided on, though the official invitation cannot be issued until after the 31st May, will be made under pleasant auspices.

---

It will be remembered that in the earlier drafts of the South African constitution provision was made for the election of the House of Assembly in accordance with the principles of proportional representation, but that this part of the scheme was ultimately abandoned, principally on account of the opposition of the Cape and Orange River Colony delegates. Mr. Merriman, who has a sturdy dislike of anything "new fangled," is known to have been strongly hostile to the idea. On the other hand, the Transvaal delegates were equally strong in its support, and Mr. Smuts shortly afterwards gave practical evidence of his faith in it by carrying through the Transvaal Parliament a measure applying the method of proportional representation by means of the single transferable vote to the municipalities of Pretoria and Johannesburg. The first election under the new Act took place in October last, and an interesting report on the results has been written by Mr. John H. Humphreys, Honorary Secretary of the Proportional Representation Society, whose services were borrowed by the Transvaal Government from the Imperial Post Office, in which department he is an official. It is noteworthy that the percentage of spoilt ballot-papers attributable to the new system was only 0.95 in Pretoria and 2.35 in Johannesburg. The higher percentage in the latter case is attributed to the cosmopolitan character of the population, and the consequent difficulty of instructing the voter in his new duties. The results show that the various groups or parties secured a representation closely proportionate to their strength, and thus what may be regarded as the primary object of the system was attained. In each case the ex-Mayor headed the poll, which would seem to indicate that the system facilitates the success of candidates with a good record of public service behind them. Press opinion on the results was, upon the whole, very favourable. Mr. Humphreys' detailed analysis of the voting should prove invaluable to the Royal Commission which has the question of Proportional Representation under its consideration at present.

---

The question of the reconstitution of the House of Lords recalls the numerous discussions which have taken place in the colonies as to the advantages or disadvantages of a bicameral system, and the respective merits of a nominated and an elective upper house. The system was exported from this country as a matter of course, and

without any particular discussion, though in the case of the Australian colonies the reason—a curious one considering the time and circumstances—was given that the existence of the upper chamber would help to bring about federation. In all the Australian colonies, the upper house was at first nominated, except in South Australia, where a strong fight was made for the elective principle. The nominated houses neither enjoy the consideration nor possess the strength of the elected; in practice they have been somewhat torpid and apt to sit infrequently. The elected houses on the other hand have a sense of power and responsibility, and enter into conflict with the lower house with much greater confidence and resolution than nominated members would show. Thus, while democratic principle favours the elective as against the nomination method, the result is to erect a stronger barrier against the lower house, and this has been seen in a long series of “deadlocks.” Moreover, the double electoral franchise is obviously undemocratic, and in most cases the higher franchise has been continually widened. That the bicameral system has survived in face of these objections is evidence that it has a practical value in the eyes of the majority. The reason for this is not only, as is so often urged at home, that an upper house restrains the Government from acting contrary to public interests or the public will, but because the system gives stability to work done. A municipal body, which is dominated this day by one side and the next day by another, freely overturns its own institutions and destroys its own work. The bicameral constitution ensures a considerable amount of respect for what has actually been done, and avoids the waste of sudden and revolutionary changes.

---

When the upper house is nominated, the Government can practically fill up vacancies with its own supporters, and in times of stress the Governor may be called upon to increase the number of members, so that immediate additions can be made. This, it need hardly be said, puts the Governor in an awkward position. It is difficult to refuse, because this means declining to accept the advice of the responsible ministers, and it is embarrassing to agree, because the object is avowedly to pack the upper house. In a New Zealand case, which caused no little stir some twenty years ago, the Colonial Office was drawn into the controversy, and the despatch which was eventually written (after a decorous interval to allow the heat of the dispute to evaporate) has always been regarded as a masterly example of the art of saying nothing in well-chosen terms.

---

A remarkable proposal was made in February before the Royal Society of Arts by Mr. R. Enook, F.R.G.S., the short substance of which was that the big municipalities in Great Britain should

acquire land estates in the Colonies, as an investment, and with a view to transplanting as many families as possible from their own district to them. He prophesied that this process will absorb the unemployed; that "the Poor Rates, in the course of a few years, will have disappeared, and there will be no inhabitants for their mean streets and slums." He urged that all the municipalities would have to do is to "acquire lands, forests, and mines in the Colonies, and to work them on business principles: and these will have yielded returns—a matter of common occurrence—with hundreds of London companies."

This is a beautiful picture, and it can only be with much regret that any incredulity can be expressed. Everyone has felt the contrast between the overcrowding and unemployment of the old country on the one hand, and the vast empty spaces which are to be found in the British Empire, and it would certainly seem that the remedy is to transplant the surplus population to the vacant territories. But when it is proposed that municipalities should carry out this work by deporting their unemployed and employing them on their colonial estates there is a formidable difficulty at the outset. Colonial life requires vigorous workers, and it is obvious that the municipal *émigrés* would not be of that class. The problem of unemployment would quickly be solved if the unemployed were, as a rule, fit for colonial careers. But this is what they are not, and any scheme which assumes that they are is doomed to failure. In short the attempt would not be on "business principles," and certainly would not be made by any of the "hundreds of London Companies." The municipal problem of unemployment is at bottom that of boy and girl labour. It is at this period that the unemployable are created, and schemes for transporting redundant population of this kind to places where better chances are offered are on sound lines.

---

If an example is wanted to show how Mr. Enock's scheme would work out, a good one can be found in a report made to the Canadian Government of the results of afforestation work provided in 1908-9 by the Leeds Distress Committee to give employment. Of 181 men engaged only 15 worked for the full 16 weeks allowed by the Act. The cost per acre came to £13 12s. 1d., whereas in the case of the permanent staff it was only £7 4s. 5d. Moreover, long experience has shown that the idea of planting a whole settlement from an old country in a new one is bad. The newcomers must take their place in the existing community and utilise its work and experience.

---

Lord Blyth has made an interesting suggestion in the interests of Imperial Development. "If an Imperial system were inaugurated under which the State offered special prizes for the best varieties of

cotton, wool, wheat, barley, oats, maize, rubber, &c., produced in each of our Colonies and Dependencies, we should be astonished at the amount of emulation which would be evoked, the number of 'considering caps' that would at once be put on, and the advance in quality that would in a very short space of time be visible; an improvement which would soon spread to every part of His Majesty's dominions." It has been objected that such prizes would be equivalent to bounties, and, therefore, open to the objections which are urged against any preferential treatment. This is hardly just. No one objects to the prizes which are offered at agricultural shows and similar occasions, and the recognition of a good sample of any product is a very different thing from the artificial encouragement of the industry. The Government grading of fruit and similar articles is in the spirit of the proposal. But it would be a long and rather invidious task for the Home Government to make selections over so vast a field. After all the produce brokers are always on the look-out for anything good, and are quite ready to push anything saleable. A great amount of investigation is continually going on into new supplies of such goods as tropical timber, the rarer minerals, chemicals, etc., and though Government departments help very much in such matters, the market is, on the whole, the best judge of what is wanted and what will serve.

---

South Africa, having been united by statute, will no doubt lose no time in dealing with the problems of railway administration. One of the points which call for early settlement is uniformity of rates. It cannot be expected that the public will tolerate widely different rates for similar services. The Central South African Railways are greatly cheaper than the Cape and Natal lines; thus, for imported flour and meat they charge 4d. where the Cape rate is 9·75d. and the Natal rate 12d. Then through rates differ widely from local rates, and under amalgamation there is no reason for this. At present local produce enjoys preferential rates over imported goods, and one result of this is that local produce is tempted away from the district even when it could be used there; thus in Natal locally grown sugar is sent away whilst Mauritius sugar is imported and used. Such breaches of natural laws bring about their own revenge. Another matter is to determine the share of each of the three Cape ports in the percentage of the overseas trade allotted to the Cape. The intention under the recent adjustment was that the Cape should get 15 to 20 per cent. of this traffic, but it appears likely that it will not secure so much, and the three ports which have spent so much to fit themselves for a big business will feel no little disappointment. It seems altogether improbable that the Delagoa line traffic will be cut down, and the remedy of the Cape lines is to encourage the development of their own districts.

The wine industry in South Africa seems to be the only one which has not increased during the last twenty years, and much discontent is felt at this failure, especially as undoubtedly the wines produced are now of much better quality. Many large districts in the Cape Colony are more or less dependent on viticulture, and it has been estimated that half the white population of the Colony live in these districts. It is difficult for these people to contemplate with equanimity the stagnant condition of the industry, when they hear, for instance, that Algeria, which in 1874 produced 4,000,000 gallons of wine, or about the same quantity as South Africa, now turns out about 130 millions. The chief explanation is that the average South African prefers whisky or beer to wine. Perhaps, after a suitable course of evolution he will succumb to climatic influences, and become a wine drinker like the inhabitants of similar regions in Europe. But at present there are no signs of such a transformation. The Cape dweller spends four or five times as much on whisky alone as the whole output of wine represents. The Transvaaler is still more hopeless. In wine-drinking countries there is no great necessity for restrictive legislation, and where such restriction exists, and can only be enforced with difficulty, it is certain that there is much excess of spirit drinking. In the Transvaal some 1,200 people—amongst them many white women—are annually imprisoned for illicit liquor dealing. Without prejudice to the claims of temperance, it may be hoped that in South Africa grain spirit may be largely displaced in time by wine. Apart from the moral aspect, the wine industry has given South Africa much of its most picturesque country and many of its most beautiful homes. Not much has been done, however, to organise the industry. Cape wine is practically unknown in this country, and no particular efforts have been made to introduce it in other British Colonies.

---

The Royal Commission has finished its inquiries in the West Indies and returns home to deliberate and draw up its report. The evidence taken brings out one point clearly, and that is that the Colonies have their own individual interests and views, and look at the question of a commercial arrangement with Canada with different eyes, according to the extent to which their trade is bound up with the United States. It cannot be expected that Jamaica, where the fruit and other industries are mostly dependent on the United States, will have the same views as other islands which are not so closely connected with the States or so much under American commercial control. The apprehension of retaliation by the United States has had some effect. It does not seem at all likely that any such idea is well founded, and a country which has so recently annexed tropical countries could hardly treat a commercial agreement of the kind contemplated, which to a considerable extent would

be the result of those annexations, as an unreasonable or unfriendly act. But if a colony is satisfied with its present trade it can hardly be urged to lower its tariff to Canada. No doubt some colonies will be willing to try an arrangement, and it will not be very difficult to select a list of articles on either side the duties on which will be lowered. Thus the duty on flour is much the same in the different islands, and could be lowered to Canada in exchange for a corresponding benefit. There is a general agreement that means of communication should be improved, and this object would of course be assisted by any scheme which provides for an increase of trade.

---

The trade movements in the Gold Coast and Ashanti necessitate frequent transfer of large sums in specie from one part of the country to another, and a note issue would to a great extent do away with their trouble. A proposal has been brought forward for the issue of Government notes of the value of £25, £10, £5, £1, 10s., and possibly 5s., and the maintenance of a coin reserve in the local Treasury of at least one-half of the issued amount of notes; the remainder of the reserve would be invested in approved securities, as in the Straits Settlements. The Chamber of Commerce in the colony have been consulted, and other replies on the whole are not encouraging. The objections usually made to such a scheme are that there is a risk of loss to the revenue, and that notes may circulate disease; but any bank is only too glad to be allowed the privilege, and there is no evidence that notes do communicate disease.

---

For a long time the Home Treasury used to discourage the idea of State notes, but their views underwent a change in 1885, when the Oriental Bank became insolvent. The notes of this bank had a large circulation, and the Governor of Ceylon, Sir Arthur Gordon, fearing a panic and without waiting for the sanction of the Secretary of State, gave the notes a Government guarantee. The case showed how easily a Colonial Government might become responsible for the notes of private banks, though it had no control over the proceedings of the bank, and the Treasury changed its views. The State alone can issue notes without regard to profit, and can therefore give absolute security and immediate convertibility.

---

An experimental anthropological survey has been conducted by Mr. N. Thomas under the Government of Southern Nigeria, and a peculiar feature of the work done is that certain phonograph records have been taken by him and are believed to possess linguistic and ethnological value. These records have been deposited at present with the Royal Anthropological Institute. The process opens up a new field in such enquiries and will no doubt be used more and more.

A recent handbook on Nyasaland issued by the Emigrants' Information Office states that European women appear to stand the climate better than men, probably owing in a large measure to their leading a less exposed life. This is not the usual experience in the tropics, as on the whole men keep their health and vigour much better than women, and this is attributed to the more out of door life which they lead, and the greater amount of exercise taken. Possibly, however, this is true chiefly of the official classes, and is less applicable to planters, who are more exposed to chills and exposure to the direct sun's rays. The maintenance of health in a hot country is something like walking on a tight rope, and a slight deviation either one way or another may be very serious. It would be unreasonable to expect that families exported direct from Great Britain to hot climates should thrive, and there is reason to believe that, even when the temperature is comparatively cool owing to the elevation of the land, the sunshine to some extent overpowers their constitution. The result is physical and intellectual deterioration, and there are unfortunately plenty of examples of it. No doubt acclimatisation is possible, but it is not to be expected in one generation, and it is an interesting question how long it takes and what is the necessary process. It must clearly be gradual. The first nomad races did not remove far in one lifetime; the wave of migration was necessarily slow, and gave man a reasonable chance of accommodating himself to changing surroundings. Only in this way can acclimatisation be secured; the laws of nature cannot be overturned by steamboats and locomotives. The hope that the British race may flourish in its tropical possessions, in the sense of being able to work physically in them, depends on a process of evolution stage by stage. This is going on in Australia and South Africa. Thus, in Queensland a great amount of sugar is now being produced by white labour, and there is every prospect that such work will increase. At the last Colonial Conference exception was taken by Mr. Deakin to a circular of the Emigrants' Information Office in which it was stated that it was very questionable whether farm labourers from this country "would be able to work on arrival under the tropical conditions that prevail in North Queensland," and he urged that such a statement was in effect a misrepresentation, as much white labour was actually being employed on sugar plantations with excellent results. Both points of view, however, may be, and probably are, correct. Most, at any rate, of the labour then being done on the plantation was by Australians, men who regularly went north at the cutting season. These include, Mr. Deakin said, some of the finest specimens of manhood Australia possesses. It does not by any means follow that the labourer fresh from this country could stand the work. The case is, however, excellent testimony in favour of the belief that the white race can, if it takes fairly gradual steps, accommodate itself to

hot climates. The essence of the matter is slow transition, and there is good reason to believe that the great British communities which live on the fringe of the tropics will in time be able to occupy them. The hope justifies the idea of a White Australia—an aspiration which is having no little effect elsewhere.

---

There are very few cases where a white race has lived for any length of time in the tropics so that the climatic effects can be seen, and the difficulty is, of course, that an exotic settlement seldom remains pure-blooded. There is, however, an interesting case in Jamaica. In the Seaford Town district there is a colony of Germans who are of pure blood as, with rare exceptions, they have refused to intermarry or cohabit with the natives. They were brought over by Lord Seaford as an industrial experiment. They have lost their language, and some of their national customs, but still preserve all the essential characteristics of their race, being industrious, sober and vigorous, and their standard of living and morality is much higher than that of their neighbours. So far the case goes to show that the European can thrive by the side of the black; but on the other hand these Germans have a considerable amount of leprosy, from which the natives of the district are free. The particular spot, however, in which the Germans live is at the bottom of a hot and humid valley, and dry salt fish forms the main part of their diet. The existence of this mysterious disease is not in itself a proof that European physique deteriorates in the tropics. A full investigation of the Seaford Town case would doubtless be interesting.

---

Pending the adaptation of the white man, it may be observed that far and away the best results in tropical possessions are obtained by encouraging the natives to produce on their own account. Both in West and East Africa the plantations run by European settlers or managers give insignificant results compared with private native productions, and the expediency of stimulating industry in this way is becoming more evident every year.

---

Nyasaland can produce the best quality of cotton, but progress has been slow, and the chief reason seems to be that the natives prefer food crops. The same thing has been seen in the West Indies, where the coolies have shown a preference for work on sugar plantations even when better terms were offered to them on other estates. No doubt the teeming plenty of a sugar or like plantation appeals more to the instinct of the native than a crop grown for industrial purposes. Nyasaland was long ago marked out as a suitable place for cotton growing, as Livingstone, who discovered it,

went there a second time in consequence of the American civil war, to investigate its possibilities for this purpose. It is believed that this was at the instance of the Queen and the Prince Consort, who had a strong feeling that Great Britain should not be dependent on slave-grown cotton. The result of the war put an end to this consideration; but Livingstone in his report urged that the industrial development of Zambesia would destroy the slave trade there. The difficulties of transport, however, prevented anything being done. A few years afterwards the African Lakes Corporation, originally a branch of the Church of Scotland's Mission, entered the field, but was crippled by its struggles with the Arab slave traders. This trade has only recently been put down, and the opening of the Shiré Highlands Railway from Blantyre to Port Herald has made a vast improvement; transshipment, however, is necessary three times before the sea is reached, and an extension of the railway to Beira is much to be desired, as well as inwards to Lake Nyasa. In the methods of cultivation the territory has now learnt much from experience. Coffee used to be planted on heavy red clay, a mistake not made now; and disastrous results followed from the use of Egyptian cotton, for which the season is too short. Live stock have given much trouble, but there is every prospect that careful crossing will greatly diminish the difficulties. There is abundant evidence that Nyasaland, which has a population of nearly a million workers, is going to be a great asset.

---

The report of the East Africa Survey Department for 1908-9 states that triangulation has been carried from the base near Nairobi to Mombasa. There are many obstacles to the work, one being that hilltops are often held in veneration by the natives as the abode of their spirits. It is remarked that on the coast fifteen miles is usually the limit of vision, but in the highlands it is forty miles. The topographical work is chiefly occupied with the Nairobi district. A "Rapid Allotment" scheme was carried out at a cost of 4-9 cents per acre. A type of beacon recommended as the most permanent is one of angle iron six foot high set in one foot of concrete and one of earth, and it is remarked that much money would have been saved by the adoption of substantial beacons from the first. It is hoped that a good deal of estate work will be completed in the succeeding year, and this will appease the discontent of settlers; but the staff have worked under great disadvantages, such as sickness and the difficulties of communication.

---

An arrangement has been concluded with the Western Land Syndicate, of Hull, under which it is likely that British Honduras will come forward as a much bigger supplier of that progressive

comestible, the banana. The Syndicate gives the Government the land on its estates required for laying the railway (the Stann Creek line), with wood and ballast, and undertakes to cultivate annually increasing areas. The railway is already completed as far as the Western boundary of the Syndicate's land, and will be laid for a further  $3\frac{1}{2}$  miles. The Syndicate has commenced cultivation, and the only difficulty ahead seems to be the scarcity of labour. Hitherto the United Fruit Co. have had a practical monopoly in the banana trade, as they have been the only customers, and the new development may introduce a more healthy position for growers.

---

The Crown Agents have sold a Uganda elephant (from India) to Mr. Carl Hagenbeck of Hamburg for £150. The condition is that the animal is not to be infested by tsetse flies, and is to be gentle and in no way ill natured. It will be interesting to see what will happen if Mr. Hagenbeck is not satisfied on these points and the elephant is returned on the Crown Agents' hands; it would perhaps be out of place in the pattern rooms. The case, however, may be the precursor of others, and there may yet be a deal over the mysterious Central African monster which has been talked of lately. This particular elephant can, we believe, look back upon an interesting past. Experiments were made with it as a draught animal, but were in the first instance frustrated by the fact that its harness burst asunder when it sighed. Special chain harness was then supplied, but the animal drew its vehicle—a heavy Woolwich truck—at a tremendous pace, regardless of intervening obstacles such as tree trunks, to the complete discomfiture of the cargo. Its value as a means of transport was impaired by the fact that its carrying capacity on tour only equalled exactly the amount of rice which it was necessary to take with it as food supply. But it contributed not a little to the prestige of British rule. The natives of Uganda, who never found out for themselves the use of the wheel, view the motor-car with comparative indifference, but their respect for the power which can tame and discipline the elephant is unbounded.

## THE EMPIRE'S TIMBER SUPPLY.

In a recent number of the "Journal" the lamentable consequences of deforestation on agriculture were discussed, and since then several reports have come to hand which show the wide range of this mischief and the rapidly increasing importance of dealing with it. It is coming to be generally realised that trees in masses are absolutely necessary to allow the beneficent rain to percolate through the soil as it should. It is not now believed that forests cause any substantial increase of the rainfall, but it is abundantly clear that, when rain does fall, the humus, mosses and roots of trees act as floors to absorb and hold up the water. But for this the uplands would be stripped of their soil, which would be washed down to the rivers, in the end choking up estuaries and harbours, and leaving desolation and sterility in the place of luxuriance and fertility. We may add here one further illustration of the evil, taken from a recent report. "China is the best instance of a land that never cared for forestry. She builds houses now of little poles, uses for fuel saplings, shrubs, herbage. Her children literally comb the hillsides for bits of roots and shrubs for fuel and fodder. The land is bared to the bone. It is a land of floods. Villages are swept away, hard-tilled fields ruined, starvation always stalks in China. Alternate floods and water-famines follow the waste of forests. And in this unfortunate country the work of destruction is still going on. Within the last century hundreds of square miles of country have been converted into a treeless, waterless waste; and what has been the result? The Hwang-Ho and the other great rivers of China are periodically flooded, and millions of lives are sacrificed simply because the forests in northern China have been cut down and never replaced. They cut off the trees, then the shrubs, then the grass, until not a single living thing remained on the mountain-sides. The rain washed the soil from the rocks. With infinite patience every year they build terraces wherever they can to save a little of the soil for agriculture. The once fertile valley-lands are covered with gravel

and rocks, the *débris* of floods. The territory that once was fertile is now bare ; its flourishing cities are falling into decay ; the land is becoming uninhabitable.

There is, however, another aspect of the matter which is hardly less important. The world's supply of timber is rapidly diminishing, and great efforts will be absolutely necessary before long to cope with the demand. All forms of building industries will suffer. Mining will become vastly more expensive, and there will be a corresponding rise in coal and iron. The railways, unless a substitute for the wooden sleeper is found, will be profoundly affected, and the cost of transportation will rise. Farming will be more expensive. Water-power for lighting, manufacturing and transportation will be affected. Irrigated agriculture will suffer most of all, for the destruction of the forests means the loss of the waters as surely as night follows day. With the rise in the cost of producing food, the cost of food itself will rise. Commerce in general will necessarily be affected by the difficulties of the primary industries upon which it depends. In a word, when the forests fail, the daily life of the average citizen will inevitably feel the pinch on every side—and the forests have already begun to fail.

The supply in Great Britain, it need hardly be said, is not nearly sufficient for its requirements. About 4 per cent. of its area is under wood ; whereas in Sweden, which principally makes up the deficiency, the percentage is 51, and in Russia and Austria-Hungary, the other two European exporting countries, it is about 34 and 30. In Germany the percentage is 25, and in France 17, and both these countries import much more than they export. The figures show how vastly behind the United Kingdom lies. The most destitute country in Europe is Ireland, with a percentage of only 1.5. The Government is now taking up afforestation, but probably this is mostly with the motive of finding work for the unemployed ; the price of land in this country, and the more immediately remunerative purposes to which land can be put, prohibit any private attempt to grow timber on a substantial scale.

In Canada the forests are of enormous extent, and seem at first sight sufficient to allay apprehension for a long time to come. The total surveyed forest area is estimated at 1,657,600,000 acres, which is more than that of the whole of the United States and Europe combined, and this does not include a vast amount of unsurveyed land. Taking the total at two billion square acres, and assuming a low average of 30,000 feet per acre, the superficial feet of timber amounts to 60,000,000,000,000—a figure which cannot be grasped. Much is heard of the destruction done by forest fires and reckless cutting, but millable timber is again produced after twenty-five years. Dr. Bell's account of the natural process of renewal is interesting :—“ The dead trunks of the larger trees generally stand

for many years after a great fire. In the summer following one of these conflagrations the blackened ground becomes partly covered by a growth of herbaceous plants, berry-bushes, and shoots from the roots and butts of deciduous trees which have retained some vitality, besides numerous small seedling trees. The huckleberry-bushes, which are very common for the first few years, especially on rocky, siliceous ground, bear abundant crops of fruit. They have sprung from large old roots, which are almost everywhere present in the thick woods, although their tops are quite inconspicuous, and bear few or no berries. In fifteen or twenty years the ground is covered with poplars, birches, willows, etc., to a height of about 30 feet. By this time the dead trunks of the old *brule* have lost most of their branches, and the smaller ones have fallen down. If we look under this growth we shall discover many healthy young conifers overshadowed by the more rapidly growing deciduous trees. At the end of about fifty years the conifers are everywhere showing their heads in the form of sharp apices, their dark colour contrasting strongly with the lighter shades of the other trees. In the race to get above the deciduous trees they develop tall trunks with the branches high up. In one hundred years the poplars are dying and falling down, and the canoe-birch has attained maturity and soon after shows signs of old age. Meantime the older conifers have overtopped the other trees, and given a new character to the general appearance of the forest. The younger conifers of various ages which have been springing up from seed every year take possession of the ground left by the decay of the first occupants, and in about 150 years the forest has again become almost entirely coniferous. Such is the rotation of crops of trees which is perpetually going on in these regions. Perhaps one-third of the whole area consists of second growths of less than fifty years, one-third of trees from fifty to one hundred years old, while the remaining third may be a hundred years and upwards." From this and the immensity of the area it follows that the supply cannot give out within any calculable period. This is no doubt reassuring from the point of view of the ultimate fate of mankind. But for commercial purposes it is necessary to bear in mind the practical limitations of distance and transport. These limitations are now distinctly asserting themselves. Mr. Sheck, a forest expert attached to the German Consulate in Montreal, in December, 1905, reported to his Government that, after most careful investigation of the matter, the time had practically arrived when, outside spruce and birch, no timber could be exported from Canada. He stated that the best quality of white-pine had almost entirely disappeared, that there were insignificant supplies of red-pine, that the supplies of low-grain timber, cedar, and hemlock were rapidly disappearing, that all valuable hardwood was at the vanishing-point; but that there were large supplies of spruce, balsam-fir, Banks pine,

birch, and poplar. For example, he found that in 1881 17,000,000 ft. of white-pine (the most important Canadian timber) had been felled and used, but that in 1891 the fall was down to 9,000,000 ft., and in 1901 it was only 2,250,000 cub. ft. Oak yielded 5,500,000 ft. in 1881, but only 1,800,000 ft. in 1891, and 100,000 cub. ft. in 1901; larch, which in 1881 furnished 4,500,000 cub. ft. and in 1891 3,500,000 ft., had practically disappeared in 1901; and so on in proportion. In fact Canada has begun to import. In 1904 she imported 11,000,000 ft. of hickory, chestnut, and cherry, and 46,000,000 ft. of oak, together with 15,000,000 ft. of pitch-pine, 2,500,000 ft. of ash, and 1,250,000 ft. of walnut.

No doubt Mr. Sheek probably alluded chiefly to the eastern provinces of Canada. But the statistics are none the less significant, and in an admirably full report on "Forestry in New Zealand," by Mr. W. C. Kensington, the conclusion is arrived at that it is certain that the forest resources of Canada will be taxed to their greatest extent before long to supply the United States and European requirements, and that the present fairly low price of timber (especially Oregon pine, which has been largely used in New Zealand) cannot be expected to last much longer.

In Australia there are many valuable timbers, but the proportion of the forests to the whole area is small, and more timber is imported than is exported. India is much the largest customer for the export. It is estimated that in New South Wales the hardwoods suitable for commercial purposes will, allowing for future growth, last at the present rate for 47 years, and the softwoods for 28. In Western Australia, the wooded area is estimated at some 98,000,000 acres; the export is chiefly of jarrah, and the depletion of this tree is proceeding at a rapid rate (about 60,000 acres per annum).

Africa has large quantities of exceedingly hard and heavy wood of the ebony class, but these are not suitable for building purposes.

In India the State forests cover one-fourth of the area, and are treated on the principle of a sustained yield, but there is not much prospect of any large supply for export except of teak and myrobolans.

It may be added that in the United States it is calculated that the timber supply will fail to meet requirements in from nine to thirty-three years, according to the allowance made for future growth. There are, on the other hand, immense forest areas in Siberia, but the difficulties are so considerable that the export is at present very small.

The general conclusion seems clear that, while there is no prospect of a world famine in timber, the supply on the whole is rapidly becoming more and more remote, with the attendant increase of cost. Every country will be compelled to make more use of its own potentialities. The British Royal Commission of 1908 stated

that a forest of 9,000,000 acres would yield the quantity now imported, and that there is a sufficient quantity of land now mostly devoted to sheep which would be suitable for timber. The cost of clearing and planting varies from about £3 to £7 per acre. In France and Germany state plantations have been cultivated for generations, and with highly satisfactory results. The advantages of cultivation as compared with natural growth are very great. The proper trees can be selected, the waste of nature is avoided, and by scientific forestry a continuous crop is yielded.

The annual growth of timber in an acre is for a long time well under £5 in value, and therefore in private hands artificial cultivation is practically out of the question. But timber deserves encouragement on public grounds. The argument that it conserves rain does not appeal to every country, but some benefits are universal. Woodlands protect against strong winds to the advantage of both fields and flocks. They act as resting places for birds, the great insect destroyers, and where they are absent plagues of insects are apt to arise. They arrest erosion and landslips. They shelter game, and sport does not interfere with the economic management.

Furthermore, though the market value of the annual growth of timber is small, it should be borne in mind that this is a raw material which lends itself to many industries. Thus the scarcity of it in Great Britain means, not merely that we have to pay for foreign produce, but that a great deal of the work done on it is carried out in the country of origin, and not in Great Britain. This is an inevitable tendency; the country which has a supply of a raw material can turn it on the spot into a more or less manufactured article more conveniently than the importing country, which would have to pay freight on the full weight of the original material. In the case of timber a considerable saving is effected in this respect, by doing work on it at the place of production, and thus the want of trees tends to drive out of the country a number of trades and handicrafts.

There are thus substantial public grounds for afforestation as a government work, or for the exercise of care and forethought in those places where forest areas are large. Where the land is in the occupation of natives, as in India and West Africa, it is particularly important that forests should be protected from the destruction which results from the habit of "shifting" cultivation. In many places this wide-spread custom is more destructive than any amount of exploitation for forest purposes, as it means the total destruction of the timber and serious injury to other territories within the same water system.

## THE RUWENZORI COUNTRY.

THE Report of the British Section of the Uganda-Congo Boundary Commission contains, in addition to the technical results of the Commission's labours, a great deal of matter of general interest. The work of triangulation was carried on in the face of difficulties of the most varied nature. The sphere of operations included the great range of Ruwenzori, with its snow-clad peaks rising to a height of nearly 17,000 feet out of almost impenetrable forest, and the Valley of the Semliki to the west of the range where the tremendous rainfall gives rise to atmospheric conditions most baffling to geographical work. Readers of Signor de Filippi's account of the Duke of Abruzzi's expedition will remember his graphic account of the perpetual rain and mist which made life almost unendurable and constantly thwarted the efforts of Signor Sella to obtain photographic records. Additional difficulty and danger was caused by the attitude of the natives in some of the districts traversed by the Commission, particularly in the Ankoli district, lying to the east of Lake Edward (formerly Lake Albert Edward).

"Shortly before the Boundary Commission arrived at Ihunga in March, 1907," writes Colonel Bright—"a Chief (Kasabanti) was attacked by the natives. His men, with the exception of one survivor, were killed, while he was taken prisoner, and on the following day murdered in cold blood. Kasabanti was employed by the Katikiro of Ankoli to collect hut tax, and possibly may have been injudicious in attempting to collect this tax from natives who were not well disposed towards the Government.

"I was requested by the local authorities, should opportunities offer while working in the neighbourhood of where this massacre took place, to arrest any natives who had taken part in it. Apparently, at first, the natives looked on the Commission as an expedition sent against them to avenge Kasabanti's death. Through fear, or perhaps in expectation of a reward, some natives brought in men said to have been concerned in the deaths of Kasabanti and his

party. They were brought to the British camp by the informers, and were arrested without any difficulty, and sent under escort to Mbarara.

“The south-west of Ankoli has always been an unsettled country, and possibly the apparent ease with which Kasabanti’s party had been destroyed encouraged the native inhabitants to attack small parties of the Boundary Commission. The mail was attacked, and small parties carrying letters or convoying stores were interfered with. A soldier within a short distance of camp was caught by a band of natives and severely wounded. A Swahili porter was killed and mutilated before the rear-guard could come to his assistance. The Congolese Commission lost three men, killed while encamped at Karambi. A small party of men drawing water in the vicinity of a camp had spears hurled at them and arrows shot into their midst.

“In April a caravan of friendly natives from the country to the west of Karambi, who had brought supplies of food, told me that they could not return to their homes on account of the open hostility of the natives, so I decided to send an armed escort with them. The caravan was attacked while on their way to their homes, and the escort was unable to return. The soldiers rightly remained where they were till they could be brought back to safety, rather than run the risk of being “cut up.” On being informed of what had occurred, I sent Corporal C. Kirkland, Rifle Brigade, with a section of Sūdānese to bring them back. The party travelled very light and rapidly, but while returning, after having been joined by the escort sent up with the native caravan, they—a party of sixteen rifles under a white man—were attacked, and were compelled to fire on the natives. One of the attackers was killed in this encounter.

“With the exception of Ruzumburu, in which country the natives were friendly, the inhabitants of the frontier districts of Ankoli caused the Commission much annoyance. Each officer and non-commissioned officer had to be accompanied by an escort while away from his camp, either visiting trigonometrical stations or sketching. The Commission was necessarily split up into small parties to enable the survey to be carried on with rapidity. Each camp had to be guarded, and porters carrying stores and provisions to the various camps had to be accompanied by an escort. The work entailed on the troops was heavy, the soldiers being constantly employed either on guard or escort duty. Small parties were often attacked and compelled to fire on the natives in self-defence. In Toro, including Buamba, to the west of Ruwenzori, Mboga, and Bulegga, the population were extremely friendly. This was especially noticeable in Buamba, which had a short time before been the scene of operations by the Congolese troops. There the natives themselves removed the barricades across the tracks on the approach of the

British caravans to enable them to pass through their villages through which the tracks in the forest run.

"The Lendu country adjoins Bulegga. Feuds between village and village disturb the whole country, which is also raided by more powerful tribes from the north. These natives are treacherous, and suspicious of white men.

"They caught two runners carrying a letter, beat one of them severely and cut the tongue of his companion nearly in half. At the same time a Swahili porter, carrying a mail and following the caravan along a narrow track through high grass, was set upon and speared to death, the murderers decamping with the mail, which was never recovered.

"Mr. J. O. Haldane, Collector, of Toro, made an attempt to arrest the men guilty of this outrage. Accompanied by a few soldiers and armed constabulary, he accomplished a difficult march by night through the mountains to the village in which the murderers were said to live. He arrived there just after dawn, but unfortunately they escaped.

"A Sûdanese soldier, accompanied by two porters, disappeared, and no trace of them was ever found. They were following one of the caravans, owing to his having misunderstood his orders, and there can be no doubt but that they were killed by the Lendu.

"Shortly afterwards, in the same district, a small party of seven men were treacherously attacked, and narrowly escaped. These were accompanied by some unarmed Lendu, who volunteered to act as guides. While some of the soldiers were drinking at a stream they were suddenly fallen upon; the Soudanese were completely taken by surprise, and found themselves in an ambush. There were numbers of the Lendu armed with spears, and till then concealed in the tall grass waiting for the soldiers to pass. They succeeded, however, in fighting their way through, and reached one of the British camps without any loss.

"The treacherous nature of the Lendu was hard to deal with, it being impossible to distinguish between friend and foe. The same natives who were apparently friendly, and brought supplies of food for sale to the soldiers and porters, were the men who waited and watched for any chance that might present itself to enable them to kill any stragglers, or ambush small parties."

The Commission lost five men killed and four wounded, while three men were drowned, and one soldier and 17 Swahili porters died of disease. The European members enjoyed good health on the whole, only one of them suffering from fever to an extent sufficient to cause serious anxiety. A special tribute is paid to the good conduct of the escort under trying circumstances, and the trained Indian signallers lent by the 4th Battalion King's African Rifles are highly praised.

Captain Jack, R.E., summarises in an interesting manner the main features of the Semliki Valley and the range of Ruwenzori :—

“The Semliki or Etuli flows out of the north end of Lake Edward along a broad, shallow valley. At the south end this valley is open, with the usual spear grass and thorn trees, and no streams. Going northwards this is replaced by the densest elephant grass, covering both the low land and the slopes of Ruwenzori; and the elephant grass in its turn gives way to forest.

“This eastern extremity of the great Equatorial Forest is here often of the greatest density, though not always tropical in character. It extends unbroken from the highest parts of Ruwenzori across the valley, and away to the west. To the eye it presents a most remarkable and unending vista of trees, whose tops have the appearance of an undulating green sea, and which reveal hardly a trace of the rivers, hills, and swamps, or the villages and inhabitants that may be beneath. Paths from village to village exist, but are often rough and indifferently marked, and without a guide it is easy to get lost.

“During the wet seasons an excessive amount of rain falls in this valley; the ground becomes sodden, and the trees and bushes of the forest constantly drip with moisture. The presence of so much humidity presents some curious effects. Every morning when the air is first warmed by the rays of the rising sun, one sees flecks and wreaths of mist rising from the mass of trees; first from the beds of rivers and streams and curiously marking their courses; later, from all parts. These gradually increase, coalesce, and, still rising, form an impenetrable bank of cloud over the whole valley, which usually hangs there all day. From the upper parts of the mountain it would frequently be impossible for days and perhaps weeks together to form any conception of what sort of country lay to the west.

“At the north end of the valley is again an open grass country covered with euphorbia and palm trees, and very level. Through it the river flows with many twists and turns to the Albert Lake.

“The Semliki is throughout its course a fine broad river from 60 to 100 yards in width. It is broken in places by falls and rapids.

“Its total fall is about 960 feet in a length of 155 miles, from 3,000 feet, the height of Lake Edward, to 2,037 feet, the level of Lake Albert.

“Lying between the Semliki Valley and the open country north of the Lake Edward depression is the long ridge of Ruwenzori, 70 miles in length from south-west to north-east and 29 miles across at its widest part. At the south end it subsides gradually into many broken foothills, elsewhere it rises with astonishing suddenness from the flat lands in its immediate vicinity. Its steepest slopes are on the western side, where also there is a greater vertical fall than on

the east. On its extreme north and south extremities are found short grass and thorn trees only, but with that exception the mountain is almost entirely covered with thick forest and elephant grass, and, except where there are native paths, is practically impassable. The forest reaches a height of a little over 14,000 feet, and above this altitude (which implies only the central and highest group of peaks) are bare rocks, ice, and snow. Rivers descend from the glaciers through deeply scoured valleys on east end west. In the snow region are a few small lakes.

“The snow peaks of Ruwenzori, which form such a striking and curious feature in this latitude, are comprised in an area of about 55 square miles in the central part of the mountain. They consist of three main groups or ‘massifs,’ that reaching the greatest height being on the west, the other two respectively north-east (Johnston’s Duwoni), and south-east of the first. North of these three are two smaller peaks visible from Fort Portal, and south is a chain of lower heights which can be seen from Katwe. The height obtained by the Commission for the summit was 16,794 feet, former heights obtained being, by Captain Behrens, R.E., 16,618 feet, and by H.R.H. the Duke of Abruzzi, 16,815 feet.

“Owing to the fact that the peaks are on the western side of the mountain, the highest points are obscured from view from the low ground on the eastern side by the intervening spurs and foot-hills. From Katwe and Fort Portal snow peaks, but not the highest points, can be seen; from the hills on the east some 15 to 20 miles from the mountain a good view of the whole can be obtained when clear.

“The western side is, however, the best place from which to see the peaks. Here the mountain falls very steeply in numerous craggy precipices and forest-clad slopes, and from the neighbourhood of Beni a most beautiful view can be obtained. The pure white snow of the peaks glistening in the rays of the rising sun, or tinged with rose colour at the close of day, offers a most beautiful view to those who are fortunate enough to see them in the brief intervals in which they are clear.

“But the summit of Ruwenzori is the most exclusive and difficult object for observation. During the months of July and August, when the Commission was working on the hills to the east of the mountain, and in a most favourable position for observing it, not only the peaks, but the whole mountain, was entirely invisible on account of the thick mist which prevails at this time of year. On the other hand, in the rainy season, when the air is clear, the highest parts are very rarely free from cloud.

“The snow line in the valleys comes as low as 13,200 feet, but on the hill-tops it appears, curiously enough, to be higher, for no peak was observed of a lesser altitude than 14,600 feet that had snow on it, except occasionally and temporarily.

"The mountain is, considering its impassable character, fairly closely populated, its inhabitants living in very neatly kept small villages in the secluded valleys, and up to a height of 7,000 or 8,000 feet."

Captain Iredell, of the King's African Rifles, contributes some valuable notes on the native inhabitants of the districts traversed by the Commission. In the kingdom of Ankoli the principal races are the Bahima and Baëro. The former occupy the position of an aristocracy; the latter are cultivators and serfs.

"In appearance the Muhima is totally different from the surrounding negroes. Except for his hair, which although tightly curled and growing in tufts is not so woolly as that of the negro, he might easily be mistaken for a very dark Egyptian. In some cases the features are strikingly aquiline, and united with a tall, lithe figure and beautiful hands and feet, combine to make the Muhima an exceedingly handsome man. A striking proof of the superiority of the Muhima is that they have penetrated as far as Mbalukwa's country west of Lake Albert, and are everywhere found installed as chiefs.

"The Baëro, on the contrary, are a distinctly Bantu race. The fact that for years they have supplied the Bahima nobles with concubines has done much to spread the Galla blood, but still there can be no doubt that the Baëro are a negroid and inferior race.

"*Religion.*—The Bahima believes vaguely in an all-powerful deity, who is associated mainly with rain, thunder, and other weather phenomena. They endeavour to propitiate various devils, most of whom are connected with the prevalent disease, by erecting joss-houses, in which food and beer are placed; otherwise the Bahima have no religion.

"To the Bahima devils, the Baëro add a considerable number of their own, the most noticeable being Magaso, who eats their bananas in great quantities."

The Bahima have some skill as ironworkers, and manufacture a graceful kind of pottery. Details are given with regard to a considerable number of other tribes, and especial interest attaches to the account of the pygmies, rumours of whose existence were so long treated with incredulity.

"The Batwa or Bambutu inhabit the Semliki forest and the extension of the Etuli forest south of Mboga. They stand about 4 feet high, and are long armed, short-legged, and very ugly, being usually distinctly prognathous. The legs are disproportionately short, the feet very large, and the body is covered with a sort of down.

"Both sexes affect a state of complete nudity. They have their own language, but usually talk a little of the language of their big neighbours.

"There can be no doubt that the pygmies are the race the lowest in the human scale found in Africa. They have no religion and no industries. No attempt is made to till the open glades, but they depend entirely on game and what they can steal from their neighbours.

"Though there are several different tribes they have no tribal organization. Each family shifts for itself, but it is the custom for a group of families to attach themselves to a big negro chief, and in return for food to assist him to fight his battles.

"The standard of morality of these little people is distinctly high. It is said, however, that when they have come in contact with Soudanese or Swahili the women quickly degenerate.

"The poisoned arrow is the favourite weapon of the dwarf both for fighting and hunting, at which they are exceedingly adept. All the wild animals living in the forest are killed for food, even the elephant. Pit-falls, snares, and heavily weighted spears are used, but their favourite way of hunting an elephant appears to be with poisoned arrows. These are shot into him, and the great beast is followed until he dies, when the dwarfs camp round the body and live on the flesh until it is finished. It is impossible not to be struck by the manner in which nature has shaped the Batwa to suit the dense forest in which they live.

"They are, strange to say, remarkably intelligent. A Mubutu was brought from Mboga to Fort Portal by a missionary, and eventually converted to Christianity. In a short time he was teaching in the school.

"Yet another race inhabits this forest area. The Banande appear to be related to the pygmies, but not of them. They are much bigger and more simian in appearance. They do not seem to be at all numerous, but are found in ones and twos hanging round the Baamba or Bavira villages. It appears that they are absolute pariahs, literally living on what they can pick up.

"They are usually rather light in colour, very brute-like in appearance, and markedly prognathous."

One of the members of the Commission spent six weeks at Karangora, at a height of nearly 10,000 feet on the northern spur of Ruwenzori, under very trying weather conditions. The whole report is a record of excellent work performed in the face of very great difficulties, and the Members of the Commission deserve warm congratulations on their achievement. The report is illustrated with maps, diagrams and photographs, the latter including a photograph of a model of Ruwenzori and the Semliki valley prepared at the War Office. Colonel Bright, by the way, remarks that both these names are erroneous.

“ Ruwenzori is merely the anglicized form of the Lu-Toro words ‘ru enjura,’ meaning ‘of rain.’ Either of the words ‘Ruenjura,’ or ‘Gambaligala,’ the Lu-Ganda name for the mountain, and signifying ‘they me hurt,’ probably referring to the strain caused to the eyes when looking up at great heights, would be more suitable than Ruwenzori, which neither means nor signifies anything. Ru-Nsoro, or the elephant’s head, is another designation applied by natives to this mountain.

“ Semliki is not the name of the river now generally known as that in Europe. The river is the Eturi, or Etuli. Semliki was a chief long since dead, who lived on its banks, and whose name has been given to it in error.”

Custom, however, has made them so familiar that they are hardly likely now to be displaced.

## THE FRENCH IN THE SEYCHELLES.

THERE is no trace of human habitation in the Seychelles Islands before the French settlement in 1756. The group lay on the road between the Portuguese fortress of Mozambique and the trade centres of Surat, Bombay and Goa, and no doubt many calls and not a few shipwrecks occurred there. Buccaneers found a convenient resting place, and there is a firm belief locally that there is buried treasure; indeed, it is said that in the Seychelles insanity usually takes this form. But these things are not history, and the records begin with the expedition of discovery fitted out from the Isle de France (Mauritius) in 1742.

The first French expedition left no trace, but in 1756 the frigate "Le Cerf" took possession, and a "pierre de possession," bearing the Lilies of France surrounded by the cordon of the Saint Esprit and surmounted by the Royal Crown, was set up as a token of sovereignty. This is now guarded as the most ancient monument in the colony, albeit the Crown and Lilies have been defaced, probably during the revolutionary period. The name was derived from the Vicomte Moreau des Seychelles, Controller of Finance under Louis XV. The captain of "Le Cerf" praised the port, but concluded that no advantage could be obtained from a permanent settlement owing to the mountainous character of the interior. So he sailed away, leaving only the pierre de possession and a flag. Another expedition arrived in 1768, and for several years persistent efforts were made to cultivate the land. They all ended in failure. The sad story of the principal exploiter is worth quoting, as it shows glimpses of a larger world.

"Meanwhile, Brayer du Barré, a person of great persistence of character and an indefatigable correspondent, commenced his enterprise on the island of St. Anne. He obtained from M. Poivre at Government expense the freighting of the 'Thélémaque' with what he felt necessary to establish himself, and succeeded in bringing, over a colony of fifty persons, white and black, from the Isle de Bourbon.

He asked for much more which he did not get, *e.g.* a company of Artillery to fortify his possessions and grants of land comprising the island of St. Anne, Cerf, Silhouette, La Digue and Curieuse and portions of Mahé and Praslin. But he spent most of his time at Isle de France in formulating further demands and in writing to the personages about the Court of Louis XV., to exercise their patronage in his favour. The list of his correspondents at Versailles affords room for reflection on the constant changes of officials both in the Colonies themselves and at Versailles. He addresses letters and maps to the Duc du Praslin, de Boyne, (whom he must have exasperated by styling him indifferently de Boyne or de Boine or de la Boyne), the Duc d'Eguillon, the Comte d'Estaing, de Maurepas, de Vergennes, and de Sartine; he demands the protection of the Chancellor, the Comte de St. Florentin, the Princess de Marsan and the Marquis de Nesle to help him. He begs of all in turn to help him and to oust his rival Gillot and the base usurper Hangard. But he dissipated his energies in asking for more and neglected the unfortunates whom he had induced to form his colony: and the day of retribution arrives. His mismanagement was denounced in 1773 by de La Perouze, who on a voyage from Pondicherry was obliged to put in at Mahé under stress of weather and reported his establishment as being in greatest disorder, the men dying of famine and occupied in destroying the turtles and tortoises instead of cultivating the land. The Chevalier de Tornay and Maillard de Meslé, who had succeeded MM. Poivre and Desroches in the administration of the Isle de France, now took action, refusing to ratify the cession of 1770, and obtained a judgment in 1775 condemning Brayer du Barré in the cost of the original equipment sent by the 'Thélémaque' five years before. This was the end of Brayer du Barré; in vain he appealed to a Minister on the ground that he was a Norman by birth; in vain he produced a certificate that at an earlier period of his life he had for three and a half years managed a lottery at Rouen. He was arrested for having invented a story of a silver mine and for having inveigled 30 or 40 colonists of Isle de France to emigrate to St. Anne's Island. He was ultimately released in 1776 and died at Pondicherry two years later."

Perhaps the French Government would have troubled itself little over the possession, but for the consideration, familiar in colonial histories, that another power would take it. The English occupied Diego Garcia and the fear arose that they would seize the Seychelles. Accordingly an officer was sent to them with detailed instructions, which are interesting as being exceedingly well calculated to stop or crush any enterprise. "It was forbidden to any inhabitant to take tortoises, carets, coconuts, and even wood without the permission of the Commandant. No person from the Isle de France might trade without written permission.—No bachelor was

eligible for a concession of land which was to be granted only to creoles of the Isle de France or the Isles of Seychelles who were married. All existing concessions were to be revised and the extents fixed in proportion to the needs of each inhabitant. No colonist might sell his property without the authority of the Administrators at the Isle de France, and any one leaving the Colony without presenting a solvent successor was to forfeit his possessions to the royal domain. Under these restrictions, the Colony was not likely to prosper, even although thought had been taken for the growth of a population which should be attached to the soil. Malavois was a prolific writer and compiled descriptions of every conceivable kind (pp. 222-318). This conscientious officer remained in the Colony until 1802 but was succeeded in his official capacity by Mr. Esnouf in 1792, whose instructions reflect the great events which were then occurring in France. He takes with him a 'reproduction' of the national Constitution agreed to by the Convention; he reduces taxation (of which the details nowhere appear); he institutes universal suffrages for the election of all public functionaries and judges and a colonial assembly voting the law; and he proclaims the general amnesty. All this must have somewhat puzzled the handful of colonists, who no doubt shouted for liberty, equality and fraternity, provided that the maxims were not extended to slaves."

The period of the struggle with England illustrated the troubles of holding an island in war time, especially when a revolution occurs at home. The Commandant Quéau de Quinssay, capitulated no less than seven times, and after the surrender in 1810 of the last French stronghold in Indian seas he remained calmly in possession and undisturbed for five years, until in 1815 the colony was assigned to England. A noteworthy incident under his administration was the arrival of 70 French prisoners who had been deported for complicity in an alleged attempt to kill the First Consul. One of these was the citizen Jean Rossegord, a well-known figure in the storming of the Bastille, and as a general in quelling the revolt in La Vendée. Convicts, however, were no more popular in Seychelles than they have been in other colonies, and in this case the revolutionary arrivals included in their subversive doctrine the liberty of the blacks. This was not to be endured, and accordingly 35 of them were put on board a ship and consigned to the tender mercies of the Sultan of Anjouan, where 29 died and the other 6 escaped.

The Seychelles Government have published a collection of documents mostly from the state archives of France which cover the period from the date of the first expedition to the cessation of French authority. The collection is due to the enthusiasm and industry of Monsieur A. A. Fauvel, and an excellent introduction by the Governor, from which we have taken extracts, sums up the leading events. It is rather surprising, in view of the smallness of the

group and the precarious nature of the tenure, to find that so much literature took place. The character and products of the island were reported on with no little detail. It was recognised that the group would not be very interesting on account of agriculture and commerce, but it was believed that it would be a valuable stopping place for refuge and refitment. Schemes of improvement were drawn up with elaboration, but nothing was or could be done with an enemy virtually in command of the seas. It was impossible to defend the place, and the only course open to the commandant when an English cruiser sailed in was to surrender with as much grace as possible. The logical completeness of French instructions is illustrated by the terms in which this case is referred to and which may be quoted as an example of good style under trying circumstances.

“ La guerre que le cabinet de Londres vient encore de déclarer vous rejette il est vrai, dans une situation fâcheuse et délicate, pour laquelle je ne puis, dans ce moment, vous donner d'autres instructions, et, (dans le cas où les ennemis se présenteraient aux Seychelles, pour y commettre quelques hostilités), que de prendre auprès de celui qui seroit chargé de cette expédition ou qui l'entreprendroit de son gré, toutes les mesures convenables pour garantir les habitans des désastres qu'un homme furieux, ou des ennemis irréconciliables, peuvent ordonner. Par conséquent, de traiter avec lui pour obtenir les conditions les plus favorables, et même pour empêcher toutes discussions à cet égard, vous pourrez proposer les mêmes arrangements que vous aviez faits en 1794. Au surplus, je m'en rapporte à votre zèle et à votre courage, persuadé que vous ne souscrirez rien qui puisse être onéreux aux colons et déshonorant pour votre nation et son pavillon.”

## WITH THE GOVERNOR ON TOUR.

(IN THE LAND OF THE SOUTHERN CROSS.)

PERHAPS one of the most interesting of the multifarious and never ending duties of a Staff Officer to a Colonial Governor is when he accompanies his Chief on a tour in the colony, away from the seat of Government, from the main trunk road, and, as may be, across country, particularly if one happens to be serving in a 'big game' country, and His Excellency is a sportsman. The preparations for the journey; orders to the different Government Departments concerning transport; the transmission of mails and telegrams to the Governor's camp at all times, wherever it may be; escort and various other arrangements as to horses, servants, tents, commissariat; who is to come and who to remain at Head-Quarters, &c., all interesting details occupying a good deal of time before the journey can be commenced. These being settled, and all official business cleared off up to the last moment, everyone ready of those who are accompanying His Excellency, we go to a new life for a time, some riding, others in a twelve-team mule wagon, the driver holding the long and heavy reins, and the conductor the whip, long enough to reach the leading mules, one loud crack of it, which echoes in the porch at Government House, and we start away. In addition to the ordinary servants, cooks, butlers, grooms, &c., each Staff Officer takes one of his own native servants who helps to pitch his tent; to cut grass, when it is not wet, to put under the waterproof sheet as a bed—a bed of grass, not of roses—and to look after his master generally. The first day out is usually uninteresting, as the camp has to be pitched a short distance from the starting point. Afterwards, day by day, the journey becomes more interesting and eventful. Herds of game may be seen; rivers may become suddenly swollen, owing to a heavy downpour of rain, and there is difficulty and danger in crossing them, because of the great volume of water, and the strong, and swift current. The roads having become heavy in consequence of a sudden tropical storm, the transport conveying the provisions, &c., may be delayed, and, travelling with it, the

servants. Dinner will then be very late, and so on; and, when it is ready, very likely, under the circumstances, the wagon containing the camp tables, stools, &c., will not have arrived, and so the Vice-regal repast will have to be served on the 'floor,' on the whitest of white tablecloths. But, in spite of all difficulties, the itinerary must, as far as is possible be adhered to. Long before the Governor arrives at a given point, the inhabitants of the country round about know that he is coming. The native chiefs come to the camp to "Salam" to the "Great White Chief," bringing offerings in kind according to their rank and wealth—an ox, chickens, eggs, grain, &c. There is quite a degree of ceremony in the proceeding. The procession with the offerings is quite formal. First a number of native girls carrying on their heads the baskets containing the chickens, eggs and grain; next a number of young men, and then the older men. These things are, of course, accepted, and some presents given in exchange to the chief of the tribe—usually blankets, of which the natives are very fond. There is great joy and excitement among the camp servants when these parties arrive, because they generally have a "Choosing," *i.e.*, all the girls form up in line and the "boys" opposite. (All natives are called "boy," even though they be 30 or 40 years of age or more.) Each girl is to choose whichever "boy" she prefers—they probably have never seen each other before, and most likely would not meet again. This is done by the girl crossing over to where the "boy" she chooses is standing and administering a sound smack on the cheek, then returning to her place. When each one has chosen there is much gaiety and laughter among the favoured "boys," and a proportionate disappointment among those who have not received the coveted smack in the face. The servant that I had with me was small in stature and plain featured (many of the natives are remarkably fine looking). Anyhow, on each occasion when there had been a "Choosing" he was passed over. He was very upset about it, and no doubt had been chaffed by the other servants who had been chosen. Having suffered for some time from neuralgia, I had with me a very small bottle of Creosote. He had seen this when unpacking my baggage. One day he came into my tent. I had not called him, there was nothing for him to do. I was in camp alone doing some work, the others having gone off shooting. I could not accompany them, having a broken collar-bone owing to my horse having fallen into a "Mere cat" burrow. And here I am reminded of a little incident that happened during the early part of a tour in a tropical part of the country. Being an invalid for the time being I had to take as much rest as possible. One morning at breakfast in the mess marquee the magistrate of the county, who was in attendance, and who shared my tent on the night previous, apologised for a disturbance he had made in the early morning, and hoped he had

not awakened me, at the same time explaining that he had been killing a snake (Black Mamba) that was crawling up my bed.

I could not think what my faithful James (his name was Jim) wanted : not money, for there was neither village, town nor store for miles away where he could spend it. With halting steps and much "Salaming" he approached, and after some hesitation explained how "his heart was sore. He had not been chosen. He was very unhappy. Would not the 'Great Chief' help him? He was sure there was some way." No, there was nothing. After some thought he said, "but the little bottle! Has not the 'Great Chief' some medicine?" Explanation as to the use of creosote was of no avail, all he wanted was "some of that." I handed him the bottle and told him to smell it, and then say if he still wanted some. That was quite sufficient. He was, however, then perfectly happy and convinced that, having "tasted" the "*Muti*" (medicine) he would be chosen at the next and future camps ; and so he was.

" MIMOSA."

## BUSINESS NOTES.

### Business Enterprise in the Colonies.

There has been recently a marked rise in the energy with which the resources of the Colonies have been studied in this country, and numerous exploitations show the willingness of the capitalist to put his money into places which are under the British flag. Not only is a great industrial rise in process in Canada and Australia, but the less developed territories are receiving much attention. The utilisation of the Newfoundland forests for newspaper purposes is noteworthy, and it may be hoped that this development will lead to the veteran colony becoming better known to prospectors and sportsmen. A company with a capital of £1,500,000 has been formed to cultivate tropical products in Papua, and as labour is the chief factor in such schemes it will be interesting to see what the company can make of the New Guinea native. The West African colonies are being ransacked for oil, and the adoption of this fuel by the Admiralty gives a great stimulus to the search. The vast soda lake in East Africa is to be brought into commerce by a railway. The fibre industry is being energetically developed. There can be no doubt that the expansion of new methods will cause an ever increasing demand for tropical products, and in the main investments of capital in such cases will be sound. Finance nowadays is carefully guided by science, and in production the degree of speculation gets smaller and smaller. The great activity of rubber companies is due to high prices, which are the result, not of any combine or other manipulations, but of the supply being overtaken by the demand. The supply of such an article responds somewhat slowly to an increased demand, and the greater output promised by the companies is even now, having regard to the proportion of natural and planted rubber which come into the market, hardly likely for a considerable time to depress prices much. The production can be increased almost with precision, and this gives great stability to the industry

as compared with enterprises where the yield is more or less speculative. Oil unfortunately belongs to the latter class. The Nigeria Bitumen Company has an enormous territory and has already spent a very large sum in drillings; they have yet to reap the advantage, but certainly deserve the credit of having established the fact that oil is to be found. Other explorers are sanguine of success, and the results of their efforts will be watched with no little interest. It will be well for them to bear in mind that the rough country encountered requires suitable drills; if this requirement had been properly studied much time and money would have been saved.

Rich alluvial deposits of tin have been discovered in the Bauchi, Zaria, Nassarawa and Kabba Provinces of Northern Nigeria, and mining operations have commenced: with the advance of the railway, this industry is likely to grow greatly and offer openings for capital. The tin is of very high quality and fetches from £6 to £8 more than Cornish tin. The Niger Company are now likely to reap no little benefit from the provident bargain, which Sir George Taubman-Goldie secured for them on the occasion of the transfer, that the Company should have a royalty on all minerals mined in its territories, but they can fairly claim the credit of discovering and opening up the field. The railway advance, to which we refer under that head, brings fruition near.

Nyasaland is another place which is undoubtedly rich in minerals, and an increase of prospecting may be looked for.

By a recent regulation, any company which desires to obtain a licence for boring for oil in Southern Nigeria must show that it has a capital of at least £25,000 immediately available. This requirement is not deterring substantial concerns.

---

### The Rubber Market.

There were previous to this year some 175 registered plantation rubber companies in this country, and their annual production was about 3,000 tons. Almost an equal number of companies were registered early this year, and it is anticipated that their production will in four years amount to 9,000 tons. But the world's production is 70,000 tons, of which Brazil alone contributes nearly 40,000, so that this anticipated addition to the supply is not a great matter in comparison with the rapidly increasing demand. The Brazil supply is not increasing despite the high prices, but no doubt there will be a substantial increase from the companies other than those above referred to and from other indigenous rubber. It is impossible to anticipate what this increase will amount to, but from a general calculation of the acreage taken into cultivation it seems probable that in four years the plantation supplies will equal the present world's output of 70,000 tons. They will thus command the market,

and probably large interests will contrive to steady and maintain the prices. A regular price, even if high, will tend to stimulate the use by manufacturers, many of whom have been seriously embarrassed by the recent violent fluctuations.

Rubber in the West Indies has so far failed to attain the profits made in the East, and one reason is that the best seeds have only been used rarely. A good deal of planting, however, is now going on, and taking into account the value of "catch crops" in the islands, the industry should prosper in suitable places.

---

### Notes on Tropical Products.

The cultivation of the soy bean is rapidly extending, and promises to be a considerable feature of West African production. It has been cultivated in China and Japan from the earliest times, but has only become generally known in recent years. It has a remarkably high percentage of protein and fat, and when used as a fodder gives excellent results. In a new place the growth is sometimes disappointing, as has happened in the West Indies; but this is because the beans do not flourish until the soil is infected with the tubercule organism. The prospects, commercially speaking, seem good.

The English oil-seed crushers have found the crushing of the bean highly lucrative, and have favoured it recently to the exclusion of cotton-seed and other oleaginous seeds. The agricultural reports everywhere are highly laudatory, and the oil can also be used in soap-making and to some extent for paints.

A great increase of sisal growing has taken place recently, and the price has dropped heavily. India is a great producer and cuts the price. The industry does very well still in the Bahamas and other very suitable places. But having regard to the market tendency, much discretion is advisable in places which are not so well favoured for the cultivation. The requirements of each locality require special study, as the life and yield of the plants vary greatly. For every 100 acres a capital of about £200, generally speaking, is required, and a large estate is necessary to support the machinery. Obviously, the industry is not one for the small planter, except in cases where co-operation is possible.

Caravonica tree cotton is the subject of many experiments, chiefly in Lower Mexico. The bush is perennial, requires little attention, begins to bear at seven to eight months after sowing, and gives a remarkable yield. Some lots have been sold in Liverpool at rather higher prices than sea island cotton. There is, no doubt, a future for this industry in hot but not excessively rainy countries. It is to be tried in Papua.

### Rubber Cultivation.

Expert opinions on this subject are now much more precise than they were not long ago, and some main conclusions may be stated shortly:—

(1.) The best tree for plantation is generally the *Hevea Braciliensis*, but not all seeds of these trees are good, and there must be selection. In West Africa, *Funtumia Elastica* produces good results and is, in many places, more free from insect pests than non-indigenous varieties.

(2.) The aim in cultivation should be to obtain the largest possible area in bark and the largest possible girth in the basal part. Wider planting is necessary for these purposes than has been usual—say 100 trees per acre. The girth is obtained by pinching the terminal bud when the tree is about 10 feet high, and this is followed by forking, but trees so treated are rather liable to fungus attacks.

(3.) The flow of rubber from the first tapping is thick and apt to harden quickly. This is prevented by fixing a drip-tin just above containing water and a little ammonia. When the latex becomes thin and watery the tree should be given a rest.

(4.) In the case of *Hevea* trees the new incision must be quite near the previous one. This is because incisions in this case stimulate and increase the flow. Good results are obtained by re-opening the old wound, removing as thin a layer of bark as possible. There are many special knives to ensure thin parings and save the bark.

(5.) A slanting cut is as efficacious as the old V-shaped cut. The best plan is to make a vertical groove in the bark from the base to five or six feet high, and then make long slanting incisions about a foot apart to it (the "herring-bone" system); the incisions yield the latex, and the groove conducts it to the ground.

---

### Cocoa.

The Southern Nigeria *Gazette* contains the following instructions:—

"The young cocoa trees should be planted at least 15 feet apart and as far as possible the ground should be kept clear of weeds, dead branches and other rubbish. Farmers should be induced to plant only such a number of trees as they can properly look after with the labour they can get. If plantations are larger than this they are certain to be neglected and they then become centres of infection for the spread of diseases due to fungoid and insect attacks. Although a farmer may for a short time get a little more cocoa from a large number of trees, yet if he has more than he can look after he will in the end lose more by their becoming diseased from neglect and the diseases spreading to other trees.

“ Where more than one main stem rises from the ground all but one must be removed by pruning ; the strongest and healthiest being generally left. From the above main stem not more than four lateral branches should be allowed to develop ; any branches in excess of this number being removed by pruning. All suckers should be removed except where they are required to replace dead or diseased trees. Where the *Amelonado* variety of the cocoa plant is cultivated, care should be taken that the main branches, which in this variety have a tendency to bend down towards the earth, are either supported by sticks or pruned in such a manner as to prevent that tendency. Once the tree has developed into the required size and shape, all weak branches and those bending towards the ground or overlapping should be pruned off. This should be done while the branches are young, since large branches should not be pruned more than is absolutely necessary.”

---

#### Brussels Congress of Tropical Agriculture.

For a subscription of 15 francs copies will be supplied of all the official publications, which will probably include a volume of papers read at the Congress.

---

#### Minerals of Southern Nigeria.

A report by Professor Dunstan shows that the sands and concentrates examined contain a number of minerals: quartz, ilmenite, zircon, rutile, monazite, tourmaline, staurolite, kyanite, felspar, and limonite. Many of them also contain gold, topaz, titanite, and magnetite. A few carry small grains of chrysoberyl and corundum. One or two contain *traces* of tinstone and columbite. But on the whole there seems no evidence so far that the minerals are of sufficient value to repay working on a large scale. There is, however, much lignite which would be of great service as fuel and might also be used for the production of gas for lighting and heating. This material may be extremely useful in cheapening locomotion.

“ Probably the chief use of the material in Southern Nigeria, at any rate at first, will be for firing locomotives and for steam-raising on river steamers.

“ Destructive distillation experiments with these Nigerian lignites confirm the experience of gas engineers with lignites in general, that they have a tendency to yield gas of low illuminating power. This, however, is of less importance than formerly, since gas is most economically employed as an illuminant in association with incandescent gas mantles, and when so used its heating power is the most important factor, the intensity of the light obtained depending on the temperature to which the mantle is heated.

"Gas from these Nigerian lignites would be quite suitable for use in this way and for general industrial purposes as a source of heat and power. Such of the lignites as are high in 'volatile matter' could be advantageously employed in this manner.

"It was observed that some of these lignites, when kept freely exposed to the air, showed a tendency to disintegrate, and this may prove a difficulty in storing the material in quantity for industrial use. This matter was referred to in the previous report (*loc. cit.*), and it was then suggested that if this difficulty was experienced in practice 'briquetting' should be resorted to. There are two systems of briquetting fuel in common use: (1) that generally used for lignite and peat on the Continent, in which the ground lignite is subjected to high pressure, when the heat thereby developed results in the formation of some 'lignite pitch' which binds the lignite together; (2) that generally used in the United Kingdom for coal, in which the ground fuel is mixed with tar, pitch, starch or other binding material, and then compressed. Large consignments of the Nigerian lignite have been asked for so that briquetting trials may be made with it, and the results of these will be dealt with in a later report of this series. It may be noted, however, that if the Nigerian lignite can be briquetted successfully this may have the effect of increasing its calorific value, and in any case of rendering it practically unaffected by exposure to air and moisture, which will materially enhance its industrial value."

---

### Lake Magadi.

It has been known for many years that a great soda "lake" lay south of Nairobi, and a concession of the territory was granted in 1904 to the East African Syndicate in the shape of a lease for 21 years. Later in the year a new syndicate came into existence with the name of the F.A. Syndicate, which appears to be a playful way of carrying on the succession, and this body acquired an option of acquiring the property, but nothing seems to have come of this. The difficulty in the path was the transport, and there was also some apprehension whether a few manufacturers and dealers who control the market would fight against the introduction of a vast amount of natural soda. There was no question about the magnitude of the deposits. They constitute a solid mass of a least 20 square miles, and are fairly pure. It is much the biggest field of the kind in the world. Eventually an agreement was concluded last year with a new company (Messrs. Samuel and Co.), which was formed to take over the lease. The main features of this document are a new lease by the Government for 99 years; the construction of a branch railway by the company from the Uganda Railway to the field (a distance of some 60 miles), equal to the standard of the latter railway; the provision of land free for this purpose; an under-

taking by the Uganda Railway to carry up to 160,000 tons of soda annually; an undertaking by the Company to despatch at least 250,000 tons in the first five years; payment to the Government of a royalty on raw soda of 2s. a ton; railway rate of  $\frac{1}{2}$ d. per ton over the Uganda Railway, subject to later revision. The Government will work on the lines on the principle of adjusting the rates to the expenses, and the Company is to provide £200,000 to meet the necessary increase of rolling stock.

Mr. F. Shelford has made a reconnaissance for the railway.

Oil as Fuel.

The discovery of oil in Nigeria and other places will, it may be hoped, lead to the use of oil for fuel locally, as though oil generally costs more than coal it will hold the field when it is produced against imported coal. After many experiments the Admiralty adopted a burner to atomize the oil which we believe has worked satisfactorily. There is some danger of fire, and a high-flash point should be obtained if the heat in any spaces in the vessel which the vapours might reach is very great, as sometimes happens in confined parts. The Admiralty flash point is 200°, which is more than mercantile practice requires. In determining a safe flash point, it should be remembered that inflammable vapour is distilled from oil at temperatures considerably lower than that of the flash point: thus when the flash point is 150° F., such vapour is evolved at 100° F.

Electric Lighting.

It is often desired to have a general idea of the cost of providing a small town with an electrical installation. A scheme providing for about 2,000 lamps (equivalent to not less than 3,000 lamps fixed in consumers' premises) over a fairly wide space, would require two units of plant, each having a capacity of about 50 kilowatts, with a storage battery capable of supplying about 100 50-watt lamps for six hours. The cheapest generating plant is with gas engines, and the cost would work out as follows:—

Two gas engines, 80-h.p.	...	...	£2,220
Two dynamos and boosters, 50-kilowatt output	...	...	880
Switchboard	...	...	500
Battery	...	...	240
Erection, say	...	...	760
			<hr/>
			£4,600
			<hr/>

If oil engines were installed the cost would be increased by £370; if steam engines and boilers, by £510. The choice turns chiefly on the local cost of the fuel required.

The other expenses may be put roughly as follows :

Building ... ..	£1,000
Distributing mains (for 17,000 yards of main)...	5,500
	<hr/>
	£6,500
	<hr/> <hr/>

Thus the whole cost would be :

Plant ... ..	£4,600
Building and mains ... ..	6,500
Contingencies (at 10 per cent.) ... ..	1,110
	<hr/>
	£12,210
	<hr/> <hr/>

A resident engineer, a skilled white mechanic, and four to six labourers would be required.

The above scheme would entail working costs of about £1,000 a year, assuming that 45,000 units were consumed, and the output could be increased to 80,000 units without any further cost except in the fuel. With a charge of 8d. per unit an output of 45,000 units would cover the working expenses, but nothing more ; with a sale of some 100,000 units at 6d. per unit sufficient income would be provided to cover all charges, including depreciation and sinking fund.

In private houses each 16 c.p. metallic filament lamp should consume from 10 to 12 units per annum ; hence at 8d. per unit the average annual payment would be from 6s. 8d. to 8s.

A fair conclusion is that if a demand is made for some 1,500 lamps this may justify making a start, as the first demand is sure to be rapidly increased owing to the fact that the uses to which the lamp can be put are more readily appreciated after supply has been given.

---

### Electric Power.

The alternating current system is convenient for lighting purposes, but for power it has some drawbacks, particularly where workshop driving is concerned. The most important of these disadvantages is the difficulty of obtaining variations of speed. A limited amount may be obtained, but at considerable expense and at the cost of much lower efficiency. With continuous current, speed variations in the ratio of three or even four to one may be readily obtained, and for machine-tool work these wide speed variations are being demanded more and more. Especially is this the case for machines with individual motors, such as the larger lathe, heavy drills, planing machines, &c., as a large number of speeds are required for these classes of work and mechanical gearing to effect

them would be cumbersome and expensive. For workshop practice there is now a general consensus of opinion that the continuous current motor is the better one.

The wiring is more complicated on a two-phase system, requiring four separate conductors to each motor, switch and starter, as against three for a three-phase system and two for a continuous-current system.

---

### Generating Plant.

To get good results from a producer gas plant, anthracite beans are the correct fuel, and the price of these may be high and the supply difficult in many places. A suction gas plant requires about  $1\frac{1}{2}$  lbs. of anthracite per kilowatt hour.

The Diesel engine uses crude petroleum, and the fuel costs are about half those for a producer gas engine. It is in use at the Hong-Kong Electric Light Station.

A 400 h.p. gas engine and alternator using gas on the suction principle from anthracite has been sent by Messrs. Mather and Platt to the Gold Coast, where it will be used to transmit power to the Taquah Mine of the Prestea Block "A" Co. The coal required is said to be about one-third what is required by a steam plant, and can be imported over the railway at a rate which makes it more economical than the local timber.

Whenever generating plants of over 700 h.p. are required, it is now almost universal practice to instal steam turbines. For small sizes steam engines are still more economical, but when the above size is reached the turbine becomes rather cheaper to work from its superior condensing power; it is also cheaper, takes up less room, and is better adapted to the work.

A turbine shaft will in time show signs of wear due principally to vibration at the pedestal bearing and require adjustment. This involves taking it down and putting it back, and when there is only a single plant this means generally an inconvenient interruption. The best plan is to duplicate the machinery or provide accumulators, but if this cannot be done the work should be stopped notwithstanding the inconvenience, as the machinery is sure to suffer if the wear is not rectified.

---

### Gas Engines.

Last year Mr. G. Lingwood, of the Waterworks Department, Barbados, investigated in this country the suitability of gas engines and producers for pumping purposes. His report, which has been printed, gives full statements of the plants offered by the leading makers, with prices.

**Clayton Disinfecting Machines.**

Several recent reports have been received on these. In the Gold Coast, 312 buildings were disinfected in six months, and much of the present security is attributed to the process. The large engine was tested in a room containing insects and a culture of *Danzon* vines, with the result that the first was killed and the second rendered sterile. The small engine was not found so efficacious as the large. In Southern Nigeria several ships have been disinfected with absolutely satisfactory results. A suitable length of hose should be ordered if it is desired to reach the hold of large steamers. In British Honduras both machines were found satisfactory, but it is suggested that the fittings should be more flexible to admit of easier handling in harbour. An additional outfit can be supplied to give greater flexibility in special circumstances, and it is not desirable to reduce the diameter of the hose (6 inches), as this reduces the efficiency of the machine.

---

**Beacon Lights.**

The Engineer-in-Chief to Trinity House has designed a simple port light showing a flashing light. It has a simple capillary burner and no complicated machinery; candle power, 3,000. It requires a light trestle to carry it. It will maintain itself in action all night without attention, but in common with other lights requires lens and lantern glass to be cleaned every day, if possible. Price, complete with tower and ladder ready for erection, about £500.

The Wigham Lights are cheaper but not so powerful, and are said to require frequent attention and adjustment.

As regards acetylene lighted beacons, the cost of a third order light with tower and acetylene gas producing plant for maintaining the light for thirty days, the intensity of the beam being 2,500 candles, would be about £1,600. The cost is less if the keepers can attend daily to the production of the gas required.

At a height of 100 feet the geographical range is about 16 miles.

---

**Particulars of Traction Engine, Wagons, and Water Tank, for Service in Somaliland.**

The engine was made by Messrs. Fowler & Co., Ltd., to War Department Specification and Inspection.

Diameter of cylinders: high pressure  $3\frac{1}{2}$  ins., low pressure 7 ins.  
Length of stroke 8 ins.

Working pressure in boiler 200 lbs. per sq. in.

The engine is capable of pulling a load of 7 tons gross on ordinary hard roads, the gradients not exceeding 1 in 12, at an average speed of four miles per hour.

Should the nature of the ground be very soft, this gross load would require to be reduced, for two reasons; the resistance of pull required to move the load is increased when the wheels of the wagon and engine sink into the ground, and the effective power of the engine to produce a pulling effort is reduced if wheels slip and do not get a proper grip of the ground.

When difficulties of this nature are experienced, it may be necessary to adopt one of the following methods:—

1st. By securing projecting cross plates known as “spuds” to the driving wheels in order to improve the grip of the wheels on the ground.

2nd. By the use of the winding rope of the engine: this winding rope may be used in various ways.

(a) Disconnect the engine from the wagon and let it proceed on ahead by itself for a distance admissible by length of rope. The wheels of the engine must then be scotched to prevent their turning or the engine moving, and the engine is then able to exert a very great pulling effort by means of the winding rope and drum. By securing a snatch block on the wagon the amount of pull can be still further increased, but this should be adopted with great care in order not to cause undue strain to the frame of the wagon.

The length of winding rope of engine is 100 yards, and a spare length of 100 yards is also supplied with the engine equipment.

(b) If the ground should be too soft or slippery for the engine to move at all, even when not secured to the wagon, it may be necessary to use the winding rope to warp the engine along. In order to do this some sort of holdfast in the ground is necessary; if trees are not available, artificial holdfasts must be made, either with picket posts or by sinking a baulk of timber in the ground.

If the ground is known to be soft and generally bad it is always advisable to proceed very carefully. It will be found to be more economical to start with very light loads to ascertain definitely what the surface will stand without it being necessary to resort to either the use of “spuds,” or the “winding drum;” of course, if bad places occur only occasionally and are not very extensive a full load could be taken, and winding resorted to if necessary, but as a general rule, it may be taken that the working load should be reduced when there is doubt about the state of the ground to avoid the necessity of the use of “spuds” or “winding rope.”

The consumption of coal and water will be found to be influenced very much by the nature of the surface of the road. The pull required to move a vehicle on a good hard level road is about 80 lbs. per ton of load, and in very soft sand the pull necessary might be increased to as much as 500 lbs. The consumption of coal varies directly as the work done, or in other words, as the pull to be exerted. What the actual consumption of fuel and water will be can only be

ascertained by trial. It is much better to arrange for a trial run, say, of ten miles, to get this information, than to get into difficulties by supplies running short.

Good Welsh coal should be used if possible, of a semi-bituminous nature, not too friable as to break up too easily in the furnace. The boiler is designed to burn almost any kind of coal, but there is nothing to gain by using a cheap and inferior quality of coal.

The amount of coal consumed will depend also very considerably upon the skill of the driver.

The boiler should be thoroughly washed out after steaming for one hundred hours. A small pump is supplied for the purpose.

When water of unknown properties is being used in the boiler of a traction engine, its action on the internal surfaces of the boiler should be very carefully watched, and any pitting, grooving or excessive deposit should be reported in order to get technical advice as to whether the safety of the boiler is likely to be affected.

The water should be tested every day or two to ascertain that it has no acidity. A small quantity of soda should be added to the feed water daily. Water can be tested by means of blue litmas paper. If the water turns the blue paper to red the water is acid, and should be run off and more soda used in future. Under no circumstances should oil or grease be allowed to get into the boiler.

If for any reason the engine is laid up, the boiler should either be completely filled with water slightly alkaline, or else quite empty, and the inside made thoroughly dry and the boiler permanently sealed, trays of lime being placed inside the boiler.

The boiler fittings should be kept thoroughly clean and free from leakage. The efficient working of injectors depends very largely upon their internal fittings being clean. The safety valve must be tested to make sure that it is free to act.

The lubrication of all working parts of the engine must receive very careful attention. Failure to attend to regular and systematic lubrication is a cause of great expense and inefficiency.

For efficient lubrication, attention must be given to the quality of the lubricant used for the particular purpose.

The lubricating oil used in the steam cylinders is "oil, cylinder, mineral," and for bearings, "oil, compound engine," and "Rangoon."

In tropical climates or in the summer in England, it is advisable to thicken the "oil, compound engine," or "Rangoon," by adding the "oil, cylinder, mineral." This applies especially to the main axle bearings.

All lubricators and pipes leading from lubricators to bearings should frequently be examined and cleaned, if necessary, to make sure that the passage is quite clear.

"Oil cylinder mineral" is also used for lubricating the axles of wagons. The axles of wagons in the tropics should be lubricated several times during the day, and frequently tested to ascertain if they are running hot.

---

### Charcoal Fuel.

Mr. D. E. Hutchins, in his report on the forests of British East Africa, makes the following recommendation of charcoal fuel made from wood. "As a means of utilising the quantity of waste wood in the forests of the Protectorate, the making of compressed charcoal bricks seems worthy of consideration. For this purpose it would be necessary to make charcoal in a kiln. This would produce besides charcoal, wood vinegar, tar, and wood creosote. One hundred lbs. of wood (dried at 300° Fah.) yield when calcined about 30 lbs. of charcoal and 70 lbs. of gaseous products. Of the 70 lbs. of gaseous products, 63 lbs. is crude wood vinegar, from which about 4 lbs. of pure Acetic acid is obtained. The wood vinegar would furnish a useful bye-product with a local sale to some extent. The wood creosote would be used for creosoting sleepers. The tar would be used for compacting the charcoal into bricks.

"There would be considerable economy in the use of such brick fuel in place of wood fuel, particularly where it had to be carried long distances, as in the case of the steamers on Lake Victoria Nyanza. It might even be possible to make it in sufficient quantities to supply the ocean steamers at Mombasa. Its calorific power would be equal to (or superior to) coal, and be more than double the calorific power of the best hard firewood. Only about half the weight of kiln-dry wood is heat-producing, of air-dry wood less, and of partially seasoned wood much less. Almost half the weight of even kiln-dry wood is useless oxygen (cellulose 49.3 per cent.; average wood about 44 per cent.). There is also over five per cent. of useless hydrogen, and one or two per cent. of mineral ash. So that chemically about half the weight of even kiln-dry wood produces no heat on combustion. This may be compared with the 81 per cent. carbon in English steam coal.

"In converting quite dry wood to charcoal in a kiln more than two-thirds of the weight goes. In making charcoal in the ordinary way the weight is diminished by three-quarters or even more, and the bulk by one-half. The economy of carbonising the wood is thus apparent, but to get the charcoal into a useful compact form that would burn well, the charcoal would have to be compressed by machinery and mixed with tar, nearly, in fact, repeating the process by which coal was made geologically. Such a process would be expensive, but, as we have seen, it would save from one-half to

three-fourths the cost of carrying wood fuel, and it would furnish creosote which is expensive stuff to import, as it cannot come with ordinary ships' cargo.

"In America, carbonising plants have been erected on a large scale in order to utilise the saw-dust from the saw-mills. This accumulates in enormous quantities and becomes a nuisance difficult to dispose of. Charcoal from these factories is produced at astonishingly cheap rates, and in quantity which is in excess of the demand for charcoal.

"The carriage of wood fuel for use on the Uganda railway forms no inconsiderable portion of the traffic at present. The traveller passes numerous trains loaded with nothing else but wood fuel. The substitution of bricks of compressed charcoal would do away with one-half or three-quarters of that carriage—the carriage chemically of a quantity of useless water and oxygen. This carbon brick fuel is free from the sulphur in coal and thus corrodes the boilers less. It also produces less smoke."

---

### Wireless Telegraphy.

It is proposed to establish wireless telegraphy at Antigua, Montserrat, Nevis, and St. Kitts. The difficulty in such places is that the principal towns are dominated by high hills and are practically screened so far as radio-telegraph waves are concerned, except in the one direction towards the sea. Thus, between Antigua and Plymouth in Montserrat the hills of the latter island intervene directly, and it is therefore advisable to select a site on the east coast.

The sites should be about 400 feet square and on high ground with a clear slope to the sea; the soil should not be rocky.

An Australian conference has advocated the establishment of wireless telegraphy between Australia and New Zealand, and New Zealand and Fiji, and generally with the Pacific Islands.

An order has been placed with Marconi's Wireless Telegraph Company for an installation between Aden and Berbera.

---

### Agricultural Implements.

The common reproach that British manufacturers do not study Colonial conditions has some basis, at any rate as regards this class of goods, and the fact accounts for the greater popularity of American appliances. One point that should be considered is the applicability of implements to dry farming conditions, where the ground is hard. Here the moldboard plough cannot be kept in the ground; the disc

penetrates better, is self-sharpening to some extent, and does not require much repair. The alfalfa renovator (American) is made on the principle of a disc harrow, and is good for pulverizing soil for grain crops. There is also an effective weed-killer, like a tooth-harrow, but hammered out at the end and with cutting parts turned at right angles to one another.

There is an increasing use of drought-resisting grain and plants, and a vast amount of agriculture will in no long time be carried out in low rainfall countries.

---

### Dried Food Products.

The portability of foods dried in such a way that the addition of water restores them to their original state makes them very convenient for expeditions and undeveloped places, but it must be remembered that evaporation by heat destroys part of the substance; thus a milk powder may be obtained in this way, but it does not become milk again by the addition of water. The proper method is to dry up the water by passing a current of warm air through the liquid in spray. The result is that the liquid is instantly robbed of its water, but no vital entities are destroyed. This is the process by which the dried egg and milk products of the Casein Company are made, and the *Lancet* states that they are an obvious advance on such food preparations.

---

### Stamping Presses.

These are frequently required for the impression of revenue duties, and in some cases, such as the duty on cheques, rapid handling is necessary. The press therefore should be self-inking; the cost of one such as is approved by the Inland Revenue is about £30, and its rate of production of stamps averages from 700 to 1,200 an hour, according to the efficiency of the operator. For long and continuous work the dies should be hardened; such a die with complete date stamps is supplied for about £10 10s. It is desirable to provide a cast-iron stand and mahogany work table top (£6 10s.).

---

### Dredging and Reclamation.

It is generally important that dredgers should work continuously at the task of deepening, and if they have to unload themselves this cannot be done. To permit continuous dredging it is necessary to provide either (1) a floating pipe line, or (2) a flotilla of tugs and barges with a floating auxiliary pumping plant. The floating line interferes with navigation, and is objectionable if the dredger is not close to the land. The barge system (which can be seen in Holland)

entails an additional plant in the shape of tugs and barges and the auxiliary suction plant at the commencement of the pipe line, and unless the works are on a big scale the expense may be prohibitive. A rough estimate for two tugs, ten 350-ton barges, and the floating auxiliary pumping plant is £60,000.

At Lagos £40,000 has been spent on reclamation works in the last ten years, and it is under consideration whether the barge system should be adopted. In favour of this it may be urged that not only are large reclamation works at Lagos required, but others could be carried out, once the plant is provided, at Forcados, Calabar and Bonny

---

### The Weaving Industry in London.

In London there are many trades being carried on about which the general public are in complete ignorance ; not the least surprising of these being that of weaving canvas hose. This is essentially a north country industry, yet for many years past the weaving of canvas hose has been carried on by Messrs. Merryweather & Sons, at their fire-engine factory in Greenwich, where a considerable quantity is turned out every week.

The operations involved in the manufacture of canvas hose are many. The yarn is received into the factory in huge hanks, part of which is known as warp yarn and consists of several strands threaded together. The remainder is called weft and contains 15 to 30 strands, according to the class of hose for which it is intended. The yarn is first taken in the hank and wound upon a ryce—(a frame-work wheel, somewhat resembling the skeleton of a windmill with the sails removed)—and from thence it is wound upon large reels or bobbins in the upper part of the winding machine. The weft yarns upon the reels are then placed in another machine and wound upon smaller rollers called “shuttle pirns,” after which they are ready for the loom. The bobbins containing the warp, however, are placed in a large frame known as a “creel,” which carries hundreds of bobbins at one time, and the ends of the yarn from the bobbins are carried through a kind of grid or comb to the beaming machine, the various threads as they converge upon one point presenting a web-like appearance. The beam is simply a large and heavy iron reel, upon which the threads, when drawn off the bobbins, lie perfectly parallel and even.

When the warp has been “made up” the beam is transferred bodily to the loom, and after certain preliminary operations have been performed by the weaver the pirn is placed in the shuttle, and the actual process of weaving commences. The shuttle flies to and fro, threading the weft through the warp, and pulling it at the

same time so as to ensure the production of a tightly woven material. As the hose is made it passes, still tightly stretched, beneath the loom to the back, where it is carried up to a beam above upon which it is automatically coiled.

After a piece of hose is completed it is taken off the loom and passed through a coiling and measuring machine, which automatically records its exact length, and here, as far as the weaving shop is concerned, its history ends, the testing being done in another department.

---

The British Central Africa Co., Ltd., which has steamers plying between Beira and Chinde and between Chinde and Port Herald, has revised its through rates, and in some cases reduced those for produce homeward, with the view of encouraging the agricultural interests of Nyasaland. The Union-Castle 1st and 2nd class fares for passengers to Chinde (from Southampton) run from £30 9s. 0d. to £47 5s. 0d., as against £35 15s. 0d. to £52 5s. 0d. by the German Line; but the Aberdeen Line from London remains the cheapest (£28 7s. 0d. to £37 16s. 0d.).

---

### **Cargo for Nyasaland.**

The Union-Castle Company, in connection with their new service with East African ports, have undertaken to take cargo, shipped by their steamers, from Beira to Chinde by craft belonging to either the Deutsche Ost-Afrika or the British India, and have undertaken that no delay will occur. The distance is 132 miles. No large steamers can cross the bar at Chinde, and all cargo has to be transhipped at Beira. The German Line has large sea-going barges towed by powerful tugs between the two places, and this of course helps them greatly to secure business. The Chinde trade is greatly increasing. Sugar, maize, cotton and tobacco have good prospects.

---

### **Shipment Declarations.**

It is unfortunately a common practice to evade the law and the regulations of shipping lines by giving false descriptions of consignments. Detection is difficult, and many a parcel of dangerous explosives is shipped under the designation of some harmless chemical. Some vessels which have mysteriously disappeared may have owed their fate to this practice. There is often no penalty at the port of discharge for the false declaration. Some time ago some cases, described as containing cow-hair, arrived at London from Calcutta.

They actually contained birds' skins, the export of which from India is forbidden ; but the customs authorities here, though they detected the fraud, were helpless, and the skins were triumphantly carried off.

Usually there is no statutory provision making it a criminal offence to make a false declaration. There was recently a prosecution at Bloemfontein for a false declaration that certain wool, which was in fact from Cape Colony, was produced in the Orange River Colony. It was argued that the purchaser would be prejudiced as a higher price is given for the Orange River wool ; but the law requires something more than a possibility, and, as it was not shown that any one suffered, the argument of fraud failed and the accused was acquitted. In the origin, of course, these declarations were called for solely for statistical purposes, and from this point of view penal provisions would be out of place ; but, if they are used for the purpose of imposing on carriers or misleading purchasers, it would seem reasonable to make wilful misstatements punishable.

## RAILWAY NOTES.

## Narrow Gauge Railways.

A writer in the *South African Railway Magazine* puts in a plea for the narrow gauge on the ground of the special circumstances in South Africa. His argument is that a narrow gauge line is right when it is not expected that the undertaking will be directly remunerative. "As it is the deliberate policy of the country to spend public funds even when a return cannot be looked for, it is evident that it is the duty of the Government to provide that transport which is cheapest in capital cost and working, and if a narrow gauge railway can do the work required, not to build a much more costly standard gauge line, which is capable of doing far more than will be given it to do." He goes on to urge that a 2-ft. gauge line can be built for one-half the cost of a standard gauge line, and that the working costs are in Natal 4s. per train mile on the narrow gauge, as against 6s. on the standard, with an equal train service.

The narrow gauge, or rather the light railway, has been in late years severely denounced by many eminent authorities. But the data vary so greatly in different localities that it would be unreasonable to apply any argument generally. In England and America the railways are private property, and if a line is built it is in the expectation that there will be eventually a paying traffic. This implies that the line must have a substantial carrying capacity, and there has been abundant experience that in these circumstances the light line is indefensible. The same experience has been established in India, where on the whole the traffic is bulky. Where comparisons have been made, it has generally been concluded that the advantages to be gained by having a light line are small and the drawbacks considerable. A large number of items of expenditure remain the same as when a heavy line is built—survey, purchase of land, fencing, stations, workshops, and so forth. In earthworks the slopes are the same in both cases, and the only difference is the

width, this difference is proportionately smaller in large earthworks, and has been put at about 3 per cent. in the extreme case of a cutting 50 feet in depth with flat slopes. In bridges, for equal wheel-loads the difference is hardly appreciable. The chief difference is in ballast and wooden sleepers; if, however, steel sleepers are used it is small. For equal loads the weight of the rails is unaffected by the gauge.

The conclusion which these facts establish is that it is unsound policy to lay a light railway where there is a reasonable chance that there may be traffic enough for a heavy line. Many a light line has come into disrepute because eventually traffic has come in from unexpected sources and the carrying capacity has been found insufficient. But it by no means follows that narrow gauge railways are never justifiable. The difference in capital cost is very considerable when large earthworks, bridging and purchases of land are unnecessary, because then the works required are limited to those which vary entirely according to the description of the line. A narrow line can negotiate very sharp curves, and in country where this ability saves expensive construction works the saving is considerable. The cost of maintenance and the working expenses are less. In Ceylon the Northern Railway, 5 ft. 6 in. gauge, cost Rs. 60,437 per mile, and the estimated cost if it had been 2 ft. 6 in. along cart road was Rs. 30,228.

It is clear that for pioneer lines intended to open up new country, where the traffic is light, the cheapest possible system should be adopted, and if the country is an easy one a light line can be adopted. Low speeds and light trains should then be the rule, and many expenses will be avoided which are inevitable where there is fast running—signals, platforms, sheds, &c. Probably only one train a day each way will be necessary, and the object should simply be to get it through somehow, so long as it effectually beats bullock or other transport. The rails should not be too heavy for the light vehicles to be used, as these run better over a fairly yielding and elastic road-bed. The rail joints should be "staggered," *i.e.*, the joints in one rail made to come opposite the middle of the opposite rail; this tends to prevent the rails from being too stiff laterally to give easy running at the sharp curves. It should not be overlooked that the cutting of a new tract and the erection of bridges and culverts can often be saved by laying a narrow line mostly along an existing road, but of course this must be above flood level.

The mistake is to build a cheap light line through difficult country when a comparatively large traffic is to be expected. The gauge itself is a secondary consideration in the cost, the nature of the country being much more important. A remarkably cheap line was the Wushishi-Zungeru, which in the first instance cost about £1,400

a mile, though further ballasting and the improvement of the bridges were proceeded with afterwards, and some Government services were not reckoned in this calculation; the line satisfactorily fulfilled its purpose in the transport of materials from the head of navigation on the Kaduna River to Zungeru. Here the country was exceptionally easy, and a surface line was obtained for almost the whole distance, and the case is very different when difficult country is encountered. The break of gauge is a very serious matter if bulky traffic is to be handled, and any line which is intended to become a trunk line should be of broad gauge.

---

### West Africa.

Proposals have been made to relay certain parts of the Lagos Railway by making deviations from the existing track so as to do away with difficult curves and gradients. An expenditure of £171,257 is contemplated. A great advantage in economical working is anticipated, as the heavy goods engines would take much bigger loads, the percentage of increase in one case being as much as 90 per cent. The elimination of sharp curves will ameliorate wear and tear of rolling stock. The case shows the importance of not accepting severe gradients and curves until it is quite clear that they are unavoidable. Large engines cannot pass round any curve sharper than one of five chains radius, and crossings should not be less than one in eight.

Good progress has been made with the completion of the buildings and ballasting on the Ilorin-Jebba section, and probably the whole of the work (to 293½ miles) will be finished and finally handed over to the Open Lines Department by June, and the cost, exclusive of expenditure on works not contemplated in the estimate, will be within the sanctioned estimate.

On the Jebba-Zungeru line better progress was made towards the end of the year; the native labourers were at first reluctant to cross the Niger and go into new country, but their fears gradually diminished.

On the Baro-Kano Railway the rails reached Minna in November. Subsequent progress has been rather slow, owing chiefly to a scarcity of labour and also to the difficulties of transport. In view of these circumstances the bridge work ahead is formidable. The task has throughout been a heavy one, and the rains of last season added greatly to it; at one time it was said that ten miles of earthworks were being washed away in a day. The original programme was extended by the decision to avoid difficult country by taking the line from Baro to Minna instead of to Zungeru, and to build a branch from Minna to Zungeru to connect with the line from Jebba;

this branch became an urgent matter as it was desired to send the materials for the Jebba bridge over it. But the result is that completion to Kano will be seriously delayed. From Minna to Jebba is about 170 miles. On the other hand, there are indications that the commercial prospects of the line will be good. The tin industry in Bauchi is likely to be a valuable asset for it, and when the railway reaches Zaria it is likely that extensions for this purpose will be mooted. The Nigerian Tin Corporation has already taken up the question, and it appears that money would be forthcoming for a branch line of 120 to 140 miles.

Good progress had been made by January with the root-wall and work-yard of the Secondee Harbour, and two temporary slipways were erected on the foreshore. At Accra the works on the breakwater extension and the jetty progressed satisfactorily, and it was anticipated that in May there would be ample water along the breakwater to enable surf boats to land their material there.

---

### British Honduras.

The necessity of clearing heavy forests and the absence of an adequate local labour supply made it extremely difficult to estimate the cost of the Stann Creek Railway, and the cost is now put at £111,000. The work has been well done, and there is reason to believe that the line is better than any in Central America (exclusive of Mexico). The cost would have been less if proper labour-saving appliances had been provided. The receipts from the open section have been as good as might have been expected and the prospects are good.

---

### Uganda.

This country is obviously one that might be made the channel of communication between Central Africa and the Indian Ocean, and a comparatively small amount of work would be sufficient to attract the Congo trade to the Uganda Railway. The Nile connects the Victoria Nyanza with Lake Kioja, a distance of 47 miles; but there are rapids, and as the country is easy, a railway could be built at low cost along the bank of the river. From the latter lake to the Murohison Falls (165 miles) the journey could be done by steamer, and a short tramway could cut out the Falls. It has been calculated that the whole journey from the Congo Free State to Lake Victoria could be done in about 36 hours, and to Mombasa in 3½ days. The bulk of the Uganda Railway traffic comes from the hinterland of Victoria Nyanza, and the development of transport facilities would attract much more.

To make a connection with Egypt it would only be necessary to lay a railway beyond Lake Albert to Gondokoro (about 100 miles), and from Alexandria it would be possible to reach Mombasa in 18 days.

In this connection reference may be made to the Annual Report on the Uganda Protectorate, which gives an encouraging account of the progress and prospects of the cotton industry :—

“Cotton-growing may now be said to be established as the most important industry in this Protectorate. It is important to the country, inasmuch as it is a native industry, and one which gives home employment to thousands of natives. The progress which has been made in Uganda in cotton cultivation is now well known, and the following table showing exports gives at a glance an idea of the progress made during the last four years :—

—	1905-6.	1906-7.	1907-8.	1908-9.
	Cwts.	Cwts.	Cwts.	Cwts.
Ginned cotton ... ..	858	3,500	12,911	10,246
Unginned cotton ... ..	—	—	4,263	12,805

Reducing the unginned cotton to ginned by calculating it as containing 30 per cent. of lint, the table will be more comparative, and the figures work out, approximately, as follows :—

—	1905-6.	1906-7.	1907-8.	1908-9.
	Cwts.	Cwts.	Cwts.	Cwts.
Ginned cotton ... ..	858	3,500	14,190	14,087

It will be observed that there is a slight decrease in the exports for the last year. There should have been a considerable increase, but the growers in certain districts, for various reasons, held back their seed cotton from sale early in 1909. It was from two to three months later than usual in reaching the ginneries, consequently a portion of the 1908 crop does not figure in the exports as might have been expected.”

### Ceylon.

The Manna Railway is progressing well, nearly half the jungle clearing being completed on the first 24 miles early in February. The small contractors had some four miles of earthwork in hand at rates varying from 15 to 20 cents a cubic yard. Contractors from India will be invited to take up work, as it is desired to use as little local labour as possible.

**Trinidad.**

Arrangements are being made to proceed with the proposed lines from San Fernando to Siparia, and from Tabaquite to Poole; but the first cannot be commenced at present owing to a legal question which has arisen with the Cipero Tramways. Extensive alterations in Port-of-Spain stations are contemplated. A loan will be required before long to cover the expenses.

---

**Renard Road Trains.**

This system has been officially tried in India, and an account of the trials is given in a Ceylon report. The report states that the driving of the motor is quite simple; any one who has learnt to drive a motor-car would soon be capable of driving a Renard locomotor.

One of the most important features of the Renard train is the system of steering adopted. Steel cables diagonally attached actuate the swivel rods of the end wheels of each follower and direct those wheels to the radius of whatever curve the locomotor is driven upon; as each axle arrives at the tangent of the curve taken by the locomotor, the wheels are automatically set to the required radius and accurately follow in the track taken by the locomotor. The accuracy and safety with which the train threaded its way when driven through congested traffic and round sharp corners in the streets of Calcutta were in every way most satisfactory.

When the train is proceeding forward the steering is directed entirely by the driver, who steers as though he were driving the motor only, knowing that the vehicles behind will accurately follow the course set by the motor. When it becomes necessary to back the train its direction is controlled by an assistant who steers the end wheels at the rear of the train by means of a rod temporarily attached, the duty of the driver being then confined to reversing the engine of the motor and steering to follow the last truck.

A trial was made of the turning capabilities of the train. To effect this a circle was described, the diameter of which, measured inside the track of the inner wheels, was 52 feet 6 inches. Subsequently another trial was made, when by the assistance of a man pulling the steering wheels of the locomotor as it proceeded on its course beyond the angle at which the steering lever would operate, a curve of 34 feet five inches in diameter was accomplished.

The train is fitted apparently with ample brako power. There are two brakes operating on a drum on the Cardan shaft on the motor, one of which is in reserve in case of damage to the other; there is also a slipper brake, which operates on the driving wheels of the locomotor. In addition to the above there is a hand-brake on

each of the vehicles, which operates on a drum on the Cardan shaft. A brake test was made on October 22nd, when the train was running at a speed of twelve miles per hour; the train was brought to a stop within a length of 12 feet without inconvenient shock."

The following general remarks are made:—

"The road on which the trials under review were conducted is sufficiently severe both in alignment and gradients, to serve as a test of the Renard train's capabilities of negotiating hill roads such as exist in Ceylon.

"Generally speaking, the trials have demonstrated that the gradients on the Ceylon roads are not too severe for these trains to travel over, and that the curves, with certain exceptions, are not sharper than they can manage.

"A train loaded with over 14 tons successfully ascended long gradients of 1 in 18 to 1 in 25, and gradients as steep as 1 in 12, and in one instance a gradient of 1 in 11 on a curve of 20 feet radius, on which it stopped and re-started without difficulty; on this occasion the engine was geared to the lowest of the four top speeds, there being, besides these speeds, four lower speeds which can be utilised on severer hills or when heavier loads require them.

"It is recommended, however, that on all roads on which it is proposed to run these trains that gradients, if steeper, be improved where practicable so as not to exceed 1 in 17 or at the worst 1 in 15, and that curves of less than 50 feet radius be eased.

"Before these trains are allowed on any road it should be first ascertained whether existing curves are of suitable radius, and whether the bridges are of sufficient strength. It should be also carefully considered whether the width of the road will admit of other vehicles passing; if not, it would seem necessary that passing places be constructed.

"The Chief Engineer of the Railway Board of India, who attended the trials, approached the Renard train representative with a view to having a modified design of the train prepared, with the overall width of the train reduced to 5 ft. 6 ins., for use on hill roads, as it was found that the train practically monopolised the whole road to the exclusion of other traffic. A revised design on these lines will in all probability be made.

"From what I have observed in the working of Renard trains during both the trials in Calcutta and Assam, I am fully convinced the competent supervision of a European engineer having a first-rate knowledge of petrol motors is absolutely essential, and that as the driving of the train requires much greater skill and mechanical knowledge than that demanded of the driver of a locomotive on rails, only European drivers, preferably those trained to drive these trains at the Daimler Co.'s works, should be employed, at any rate until local drivers have been trained and found competent.

"It cannot be stated too emphatically that the staff in charge of the Renard train, including the leading mechanics at the depôts, should be the best obtainable.

"In order that the best results may be obtained in the cost of running and maintenance, the best course would probably be that the pay of the drivers be fixed on a basis of fixed pay and mileage performed, so as to conduce to careful driving.

"It has been frequently shown during the trials that no necessary expenditure in keeping the train in thorough repair, in the pay and sufficiency of the staff employed, and in the supply of lubricants should be grudged, and that ample time should be arranged for periodically, say every six months, for thoroughly overhauling the motor, otherwise increased cost of maintenance, unreliability of running, and unnecessary depreciation in the value of the stock will assuredly follow.

"An ample supply of spare parts should be at all times available.

"Trains running on hill roads with constantly varying gradients should not be overloaded, so that the necessity for changing speed and the resulting damaging effect on the gearing may be avoided as much as possible.

"It was noticed during the trials that when the train exceeded 9 to 10 miles per hour, the rear wagon swayed a good deal, and as swaying is attended with danger, a limit of speed should be enforced."

On the important question of the effect of the train on the surface of the road, the following observations are made :—

"With a view to forming some idea as to what damaging effect the train produced on the road surface, I examined the surface several times after the train, both when running light and when heavily loaded, had passed over the road ; but the effect was so slight that none was observable.

"In considering, however, to what extent roads may be affected by Renard trains as compared with known results of cart traffic, the following points should receive attention :—

"(a) The heaviest loaded axles in the train are furnished with wheels having tyres 8 inches wide, and the weight on each of these wheels is 2 tons 1 cwt., this will give a pressure on the road surface of 5·2 cwts. per inch breadth of tyre ; whereas in the case of a loaded bullock cart, the gross weight of which is say 2 tons and the wheel tyres 1½ inches wide, the pressure per inch breadth of wheel tyre is 11·4 cwts., or more than double that in the case of the Renard train.

"(b) In addition to the lesser wearing effect of the train on the road surface that may be expected for the reason shown in (a) above, a still further reduction in the wear may be looked for owing to the train being spring-mounted on all axles, whereas bullock carts are without springs.

“(c) In the ordinary nature of things trains are not driven along one track, such as bullock carts follow; the wear is therefore distributed over a greater surface of the road, and less destruction to the road should result.

“(d) On the other hand, the higher speed of the Renard train will doubtless cause greater wear than the slower moving bullock carts.

“(e) Again, when the road surface becomes worn and depressions are forming, the increased hammering effect on the sides and bottom of each depression, which would result from the greater speed of Renard trains, would unquestionably tend to destroy the surface more rapidly.

“(f) The diameter of the wheels of the Renard train being somewhat shorter than those on bullock carts, the weights are distributed over a less area of contact with the ground, and would therefore have a slightly more damaging effect, more especially when depressions are forming.

“Though it is impossible to calculate or foretell what wear on the road surface may be produced by Renard trains, and consequently to what extent the cost of maintenance may be affected, it would not be surprising if experience eventually showed that such heavy transport travelling at higher speed than bullock carts proved far more destructive than the latter.

“When roads are worn, the speed at which trains are driven should be reduced otherwise destruction of the road surface would inevitably be hastened.

“To obtain the best results, both in reduced cost of upkeep of roads and in lessening the damaging effect to the machinery of the train that would follow from jolting over uneven surfaces, roads should be maintained in as good order as is practicable.

“On roads where Renard trains are running excessive camber to the surface should be avoided, so that the full width of the wheel tyres may bear upon the ground.”

---

### Oils.

There are standard specifications for the various oils required for railway purposes, but it would perhaps be hazardous to say that such specifications cover the whole ground, and that oils made under them would be uniformly the same. Uniformity is practically secured by adopting established brands of well-known makers; but there is much uncertainty as to which are the best. Considerable value, therefore, attaches to a Ceylon report based upon experience of various kinds. For loco. engine oil the “H.H.” oil of the Vacuum Oil Co. is recommended; for cylinder oil, Messrs. Wakefield & Co.; for carriage axle oil, the Vacuum Oil Company’s Indian carriage axle oil.

### Fire Resisting Applications.

It is often desirable to protect timber on railways from fire, and there are some fire-resisting paints on the market which appear to be to some extent effective. The painting must be renewed if there is much wear. The methods of immersion in a chemical solution are not believed to be very lasting in their effect. A certain amount of protection is afforded by a coating of Portland cement wash or white-wash. This is inexpensive and easily renewed.

---

### Carriage Roof Lamps.

Leakage of oil is a common nuisance, but it is often largely due to want of proper care in filling and trimming. The oil chamber should be filled to overflowing before screwing the cap into the opening, and the leather washer should be so tightly screwed into position as to form an absolutely air-tight bearing, for if the slightest quantity of air is left in the chamber, or if the cap joint is not made perfectly air-tight, the air will act on the top of the oil and force the oil through the pipes and out past the wick. The lamp should not be re-lit without refilling the chamber. If a thinner quality of oil than colza is used the tendency to leak is greater.

---

### Tare and Load.

With full loads the bogie wagon of large capacity has an advantage over smaller vehicles, as the proportion of tare to paying load is less in a bogie wagon than in a four-wheeled wagon. Wagons of a tare of 4 tons 2 cwt. are found to carry 8 tons, and of 8 tons 19 cwt. to carry 15; while a bogie of a tare of 15 tons has a carrying capacity of 40 tons. But in places where it is often difficult to find full loads this advantage may be outweighed, and a limit of capacity to say 20 tons may be advisable. The ratio of tare to capacity is reduced by the use of steel.

---

### Axle Greases.

These in hot climates sometimes deteriorate greatly and become so thin as to be unfit for use. The process begins with a loss of water by evaporation, and this liberates fat particles and lowers the melting point. Even if a sample shows a sufficiently high melting point, if the barrels are filled before the grease is cooled and set the grease is deleteriously affected by movement. It should therefore be provided in the contract that this grease should be perfectly cold when put into barrels. The amount of water should not exceed 50 per cent. and the melting point should not be lower than 180° F.

### The Undergrounds.

The increasing necessity for underground communication is illustrated by the construction of a subterranean system entirely for goods and mails. It need hardly be said that this is in Chicago; but other large towns are likely in time to copy. Not only is a new line added to the facilities for transport, but the advantage for loading and unloading are enormous. In an open air system a great amount of labour is required to get the goods to the tracks, but here the business houses load and unload direct by elevators from the line and connections into their buildings, and *vice versa*. All the cartage in fact of every kind is done by the railway, and this frees the open air building from much encumbering traffic, and makes it more convenient for general purposes. Another use of the line is to take away excavated earth where new buildings are to be erected, so that the workmen have merely to shoot the stuff down a chute into the cars. The railway is a paying concern.

---

### "Powellising."

It is claimed by the Railway Departments of Western Australia and Victoria, that "Powellising" renders the seasoning of timber unnecessary. The Powell process consists of heating green wood in a solution containing 30 per cent. of molasses. The boiling point of this is several degrees higher than that of water. The result is that the watery matter (sap) in the woods boils first. It is driven out of the wood cells, together with any air they contain, escaping through the solution in the form of bubbles. As soon as the ebullition ceases the solution is brought rapidly to the boiling point, and it is then allowed to cool off. The wood cells, which at this stage may be likened to those of an empty sponge, gradually absorb the solution. After they have become filled, and the time will depend on the size of the piece treated, the timber is taken out of the boiling vats and is placed in steam-heated kilns to get rid of the superfluous moisture. The cells now contain a saccharine matter which, through chemical change, has become part of the wood itself, and the effect of this "Powellising" is to make the timber impervious to dry rot, and to the attacks of white ants, which give considerable trouble in the northern parts of this State.

---

### Insects and Railways.

The passenger train from Mombasa was recently held up three times between Makindu and Kiu. The causes of the stoppages were millions of caterpillars crossing the line. The engine wheels crushed the insects, and the juices from the bodies made it impossible for the

wheels to obtain sufficient grip on the wet rails. The driving wheels revolved, but on the same spot on the line. The difficulties were overcome through the stoker walking beside the engine and throwing sand down on the rails.—*East African Standard*.—The common black ant was the cause of two goods trains being considerably delayed near Sherwood Siding lately. On the second occasion it was some four hours before the driver was able to leave this extraordinary pest behind. It seems that whole hosts must have been on the march and crossing the railway lines in bands of about a yard broad, with intervening spaces, for a distance of fully half a mile. The wheels skidded to such an extent on the slain masses that the trains were brought to a standstill.—*Rhodesian Herald*.

---

### Construction and Revenue Accounts.

It is important that all railway expenditure should be brought to account properly, and the general principle is that the capital account should bear the cost of all new works and plant, and all improvements of and additions to old works and plant; while the revenue should bear the cost of repairs and renewals incurred after the opening of the line.

The following average figures of the world's railways are useful as a basis for comparisons. The gross revenue per train mile is 6s. 7d.; average cost of running a train one mile, 4s. 2d.; average profit per train mile, 2s. 5d.; proportion of ordinary expenses to gross revenue, 63 per cent.

## MEDICAL NOTES.

**Anchylostomiasis, as it occurs in Barbados.** (By C. J. MANNING, M.R.C.S., L.R.C.P. (*Barbados*).)

The disease was recognized long before the discovery of the minute creature that causes it. The result is that it is known by a great many names. During the construction of the Mt. Cenis and St. Gothard tunnels it played havoc with the health of the workmen; they rapidly lost strength and became unfit for hard work. The death rate was high, and seriously interfered with the success of those great engineering undertakings. It was there known as "La maladie des tounells" or tunnel anæmia. It is known in the French West Indies as cachexia aqueuse, Malocœur and mal d'estomac des negres. In the Brazils it is oppilatis cançao or opilacao. In Ceylon it is known as Beri beri. Some authorities assert that in Assam it is known as Kala azar, and there it is a very fatal disease.

It is also the cause of brick makers' anæmia, miners' cachexia. Egyptian chlorosis and tropical chlorosis. As soon as the parasite was discovered which causes the disease it was known as anchylostomiasis, Dochmiasis, or better still as *miners' worm disease*.—

The disease has long been known in Egypt, Westphalia, Hungary, Germany, in the mines of Cornwall, Australia, India, Ceylon, South America, and West Indies, as a matter of fact in all tropical and subtropical countries.

It is essentially a disease of poverty and malnutrition. It is not a very difficult matter to rid a patient of the worms, but the trouble usually is that he goes back to the contaminated water from which he got the disease. The real remedy is sanitary improvement, and this is often difficult to carry out. The following remarks of Mr. Manning may be quoted as supporting the view put forward in our last number that quarantine is not the way to deal with the mischief.

"There is a great want of uniformity in our sanitary system throughout the eleven parishes of this colony, and we sorely need

a properly organised department of public health. Each vestry has its own ideas of sanitation, and as most of the vestrymen are not skilled sanitarians, and as unfortunately parochial medical officers are as a rule not appointed on the sanitary board of a parish, widely different methods are adopted by each board for regulating the sanitation in the parish immediately under its control. Economy rather than efficiency seems to be not infrequently the guiding principle, and the inevitable result is that in the event of an outbreak of any epidemic in a parish careless in its sanitation, a disease like yellow fever thrives and spreads amid the filth, and defies the so-called sanitary authorities, in spite of sulphur fumigation and in spite of a steady, persistent and often futile destruction of the *stegomya fasciata*. A nucleus is thus formed in these insanitary districts from which disease spreads and invades other parishes more careful in their sanitary arrangements. Trade is seriously interfered with—stringent and often absurd quarantine rules are enforced too late to do much good, except to interfere with commerce, and practically bring to a standstill all free intercourse with other ports. Tourists cease to visit the island, steamship companies avoid us, and we have to spend thousands when a few hundred rightly applied might effectually have saved the situation had we been properly armed with all the necessary precautions of modern preventive medicine.

“Our sanitary relations with neighbouring colonies are by no means satisfactory, and in our efforts to stamp out diseases that are *endemic*, diseases that under certain favourable climatic conditions periodically make their appearance in our midst, whether we have quarantine regulations or not; we are only successful in destroying our intercolonial trade, and of breeding bad blood amongst our neighbours with whom we ought always to be on terms of good agreement, our intercolonial trade is paralysed, and our financial losses terrible.

“In making the above statement it must be clearly understood that I have not the least intention of speaking disrespectfully of our vestry system, but I do wish to make it clear that as far as relates to the sanitary government of the colony we are far behind the times, and present arrangements are not suited to the requirements of modern preventive medicine. No doubt the vestry system is right in principle and is one of the strong bulwarks of our time honoured constitution, and I should at all times be amongst the first to support and defend it by every means in my power, but nevertheless as far as sanitation is concerned it needs very thorough and careful remodelling because it is altogether out of date.

“Everlasting change seems to be one of the inevitable attributes of all true progress, and whilst no sane man could for a moment doubt that firearms are necessary for success in war, and in

sport, we must admit that his chances of success would indeed be small who persistently clings to obsolete methods and takes the field with either arquebus or flint and steel.

"I honestly believe it would be better to do away with our present quarantine restrictions altogether, and have all persons coming from an infected port kept under strict medical surveillance until such time as is considered safe to withdraw it. If any infectious or contagious disease appears let the patients be removed at once to Pelican island, or any other convenient isolation hospital, and at all risks let us look around and see what other ports like New York or London are doing ; and above all other considerations let us avoid everything like hysteria whenever we contemplate the formulation of quarantine regulations."

---

### Pellagra.

An influential committee has been formed to raise a fund of £1,000 to meet the cost of an investigation into the causes and nature of the disease known as "pellagra." This disease has during recent years been widely prevalent in parts of Italy, France, Spain, and Roumania, and has now been discovered to be of frequent occurrence in tropical countries. The malady is of an essentially chronic character, and chiefly affects the cultivators of the soil. It usually commences in the spring, and appears in the first instance as a general *malaise*, accompanied by a red rash upon the skin, limited to the unclothed parts of the body, and looking like a severe sunburn. About July or August of the first season the symptoms disappear ; but the spring attack of the second year is usually more severe than that of the first ; and with each successive year the patient becomes more like a mummy, his skin shrivelled and sallow, his muscles wasted, his movements slow and languid, and his sensibility diminished. After a certain stage the disease passes into a profound disorganization of the nervous system, with partial paralysis of groups of muscles, and in the more chronic cases these symptoms often terminate in hopeless insanity. A large number of pellagrous peasants end their days in lunatic asylums, while many more drag out a miserable existence in their native villages. The changes discovered after death are all of such a character as to indicate a general tissue degeneration, more especially of the brain and nervous system ; but the tendency to melancholy, imbecility, or mania, and the curiously mummified state of the body, are quite peculiar to the disease, and point to some special cause for the group of symptoms with which they are associated.

The disease was for long supposed to be due to the extensive use of damaged maize as an article of diet ; but the known area of its incidence by no means coincides with that of maize consumption, and

it has now been proved to exist in areas where maize is not a common article of consumption.

It is seriously prevalent in many parts of the British Empire and its dependencies. It is common in Lower Egypt, where in certain villages Dr. Sandwith found as many as 36 per cent. of the inhabitants to be affected. Dr. Lavinder found it to be still more common in Upper Egypt. Drs. Cuthbert Bowen and G. C. Low have recognized it in Barbados, and several authors have mentioned its occurrence among the Zulus and Basutos in South Africa. At the Tropical Section of the meeting of the British Medical Association in Edinburgh, Dr. Sandwith showed pictures and photographs of pellagra which were independently recognized by three members from India as representing a condition which they had often seen among out-patients without knowing its name; while Dr. U. Ray wrote in 1902 that he had observed several cases during a short stay in one of the districts of North Behar. When we take into consideration the slow course of the disease, its ordinary limitation to field labourers, and the improbability of a correct diagnosis in places where it is not frequently encountered, it is not surprising that in many places pellagra should have escaped observation among the natives of tropical countries. Its early recognition is, nevertheless, a matter of grave importance, for wherever its occurrence has been noted for any length of time it has shown a marked tendency to slow but steady extension. During recent years it has become increasingly prevalent in many parts of Italy. In the United States a few sporadic cases had been observed from time to time, but since 1906 the disease has rapidly increased, and numerous cases have been reported from thirteen States. Such a tendency to spread calls for very serious attention, when it is considered that the disease when once established in a locality remains there; and it is difficult to overlook the example afforded by sleeping-sickness of a disease which, long believed to be also a food disease (manioc poisoning), or a form of nostalgia peculiar to the transported negro, has suddenly invaded the greater part of Tropical Africa.

Among the various hypotheses concerning the causation of pellagra which from time to time have been formulated and abandoned, that which attributed it to the use of diseased maize has been the most warmly advocated, but with very little agreement as to the precise manner in which the result was brought about; whether by some noxious chemical agent generated in the maize itself by decomposition, or by the growth in it of some micro-organism. The more closely the maize hypothesis was considered the greater became the difficulties in the way of accepting it; and, at the meeting of the British Medical Association in 1905, Dr. L. W. Sambon, after calling attention to these difficulties, suggested that, in all probability, pellagra was protozoal in its origin; that is to say, that, like sleeping

sickness and syphilis, it was dependent upon the presence in the blood of a microscopic living organism. This organism, in the case of sleeping-sickness, is now proved to be communicated to man by a variety of the tsetse-fly; and Dr. Sambon believes sand flies to be the most probable carriers of pellagra. Dr. Sambon holds a very prominent place among the investigators of blood parasites, both in mankind and in the lower animals, and his suggestion has been accepted as a highly probable one by a number of skilled observers in many of the countries in which the disease is prevalent. Not the least significant of the facts by which it is supported is the favourable action of arsenic in the treatment of the disease, as in that of the declared trypanosomiotic affections. Dr. Sambon's hypothesis has received the support of Sir Patrick Manson, who not only endorses it in the new edition of his book on tropical diseases, but has repeatedly urged the necessity of investigating pellagra on account of its prevalence in Egypt, in the West Indies, and in other localities. It is certain that the time has come at which the disease should be studied by the light of existing knowledge of the action of insects in the diffusion of parasites, knowledge which has thrown so much and such invaluable light upon many of the most obscure problems of tropical pathology.

It is intended that Dr. Sambon should himself proceed to a pellagrous area in order to investigate the conditions of the disease, and the various bloodsucking flies which are to be found there. His previous experience in the study of the protozoal parasites both of man and of the lower animals renders it probable that, if there be such a parasite in pellagra, it will not escape his observation. It is also intended that he should be aided by properly qualified assistants, and that any important results which he may obtain should be studied with a view to confirmation by other members of the committee, who will either work at the material sent home, or, if necessary, will join Dr. Sambon in the field. Arrangements will also be made for the co-operation of native medical practitioners and naturalists.

The Colonial Office has contributed £150 towards the fund, and contributions have also been made by the London and Liverpool Schools of Tropical Medicine.

---

### Enteric Fever.

A further White Paper (Cd. 4712) has been issued containing a report by the Director-General of the Army Medical Service on the transmission of Enteric Fever by "chronic carriers." Particulars of the treatment of a number of cases by the administration of lactic acid bacilli and other means are given, but while it appears to be shown that the degree in which the patient is infected can be mitigated, there is as yet no conclusive evidence of the possibility of a

complete cure. It is suggested that in the "chronic carrier" the typhoid bacilli in the organs are surrounded by areas of dead tissue through which no curative agent can penetrate, and that until the contents of these areas have been discharged—a process which may take some years—no cure can result. Particulars of recent outbreaks believed to be due to the "chronic carrier" are given.

---

### Sleeping Sickness.

A despatch by Sir Hesketh Bell containing a Report on the Measures adopted for the Suppression of Sleeping Sickness in Uganda has been published in the Miscellaneous Series of Colonial Reports (No. 65, Cd. 4990. Price 5d.) It is a document of exceptional interest, containing a full account of the first appearance and spread of the disease in the Protectorate, the discovery of its cause by Sir David Bruce, the various efforts made to cope with it, and the final adoption and successful completion of the immensely difficult policy of removing the entire population of the fly-infested areas to districts outside the danger-zone. Upwards of 100,000 persons have been thus removed, and it is a tribute to the extent to which the Uganda Government enjoys the confidence of the natives, that it has succeeded in carrying out this gigantic task with the assistance of the native chiefs without provoking any serious degree of discontent. Sleeping Sickness remains at present an incurable disease, and the only methods by which mortality can be reduced are the destruction of the tsetse-fly which conveys the infection and the removal of the population from fly-infested areas. The former operation has been carried out on a considerable scale, but it cannot be entirely achieved. The success which has attended the latter may be gauged by the fact that the deaths from the disease in Buganda and Busoga, which are estimated to have exceeded 200,000 between 1898 and 1906, fell to about 5,000 in 1907 and to 3,662 in 1908, while the returns from the Kingdom of Buganda for the first six months of 1909, showed a mortality of only 459. The Sleeping Sickness Bureau has issued the 13th, 14th and 15th numbers of its Bulletin, and has also published two skeleton maps showing (1) the present distribution in tropical Africa of Sleeping Sickness and the different varieties of tsetse-fly, and (2) that of Sleeping Sickness and *Glossina palpalis* only.

The Advisory Committee for the Tropical Diseases Research Fund has issued its report for 1909. The contributions made to the Fund by the Imperial, Indian and Colonial Governments are, it is satisfactory to learn, to be continued for a further period of five years, and the Committee state that there is a prospect of further small contributions from Colonies which have not hitherto contributed. The Appendices include reports upon the measures taken to combat malaria in the different tropical Colonies.

The Colonial Services Supplementary Estimate passed by the House of Commons on March 3rd included the first instalment of £1,000 for the promotion of entomological research in connection with tropical diseases under the directions of a Committee over which Lord Cromer presides. It was received with warm approval, Sir William Collins and Doctor Addison, who speak with expert medical knowledge, emphasizing the importance of the work.

---

### The Veterinary Bacteriological Laboratories, Transvaal.

The study of cattle disease is of the first importance to South Africa, and it is very satisfactory that excellent provision has been made for it. In 1896 the country was devastated by rinderpest, and one result was that some laboratory premises were provided in 1898; in the first session (1907) of the new Parliament under responsible government, the matter was taken up wholeheartedly, and a sum of £40,000 was voted for new buildings. On the 1st of October, 1908, the premises were ready for occupation, and are on a scale that will compare with any similar institution in Europe.

An excellently written and illustrated report has been issued describing the equipment of the buildings, and containing several expert essays. Certain cattle diseases, such as anthrax, are caused by specific bacteria, and others, such as rinderpest, though due to ultravisible organisms, are spread by direct contagion; all these are non-tropical, in the sense that they exist in cold climates. The tropical diseases are either due to protozoa, or to specific ultravisible organisms which are, like protozoa, dependent for their propagation on a host in the form of a tick or an insect (heartwater, horse-sickness, blue-tongue). These latter are more or less new to science, and in their case immunity by means of injected virus is more difficult to obtain. Experiments and observations are being made on a large scale, and the institution takes its place among the first of its kind.

---

### Beri-Beri.

An inquiry concerning the etiology of this disease, by Drs. Fraser and Stanton, has been published at Singapore. A number of observations made it clear that the disease has its origin in, or at least an intimate connection with, white rice, and that it did not appear when, under similar conditions, parboiled rice was eaten. But no organisms were found in patients which could be considered causative agents of the disease, and further investigation will be undertaken with a view to discovering the cause.

**An Insect Destroyer.**

A notice has been promulgated in the *Jamaica Gazette* that a mixture called "Paranaph," for the extermination of fleas, may be obtained from the Jamaica Agricultural Society at 2d. per pound. The mixture is stated to destroy fleas with perfect certainty, and a room thoroughly washed with this emulsion is freed from insect life. With one gallon a room 12 ft. square can be thoroughly treated in five minutes. It is a special mixture of kerosine oil, soft-soap and naphtha, and can also be applied to the destruction of scale-insects, green-fly and (with certain additions) ticks. It can be made up in this country.

---

**The Analysis of Drugs.**

Messrs. Evans, Sons, Lescher and Webb, Ltd., have issued notes of the examination of various products which are especially interesting as bearing on the question of adulteration. It is satisfactory to find that commercial samples are with few exceptions practically pure. The remarks on quality deserve the attention of medical authorities.

---

According to the *Lancet* an excellent means of ventilating bungalows in hot countries is to erect a zinc shaft 10 ft. high with a hole 22 ins. square in connection with the top of the room. It should be painted black. Air is admitted through a similar but horizontal shaft on a verandah with a diaphragm formed by a wet sheet.

## REVIEWS AND NOTICES.

**Orangia:** Geological and Archæological Notes, by I. O. JOHNSTON  
(Messrs. Longmans, Green & Co. 10s.)

The main industry of "Orangia" is farming, and the population is on the whole fond of the calling and contented with its life. The disadvantages, however, are great, and it is not surprising that no little disappointment has awaited the enthusiasts who believed that great developments were possible. The chief difficulty is that the suitable land is in the possession of a small number of owners, who will neither sell to others, nor themselves introduce up-to-date methods. This quality of steadfastness, while excellent in some respects, is apt to prove inconvenient to other people who are in haste to improve the world. Then the greater part of the country is semi-arid. This would not be gathered from the statistics of the rainfall, which is fairly plentiful, but it is in the shape of torrential falls, which are largely wasted. The third trouble is the locusts and insects. The locusts at times are so thick as almost to obliterate the sun, and their depredations are terrible. A great campaign, such as has been conducted in other countries, will have to be carried out against this plague before agriculture can thrive. The want of rain is not fatal. The remedy is dry-farming, and, as has been remarked elsewhere, a great future lies before this process in such countries.

Naturally the outsider takes more interest in the mineral character of the state. Of this Mr. Johnston gives a full account, and the description of the diamond mines is a valuable one. There are also chapters on the prehistoric implements which have been found in considerable quantities, and a delightful series of illustrations reproducing aboriginal pictographs and rock-paintings. It is curious to notice that the earlier engravings showed a free and bold power of drawing which becomes stiff and conventional in the later. This seems to have been the case in Europe, and is one of the signs of the closer attachment of the more primitive races to nature. The animals, as Mr. Johnston observes, show real artistic merit; when the

human figure is attempted the result is grotesque in the extreme. This grotesqueness is not due merely to inability to draw; the primitive drawing is not a copy of things as they are seen, but an expression of what the worker knows and thinks, and thus the human figure is shown in a way which brings out the points, such as tallness, or some movement, which the worker thinks most of, and is therefore without any sense of proportion.

---

**To Abyssinia through an unknown Land :** An account of a journey through unexplored regions of British East Africa by Lake Rudolf to the Kingdom of Menelek. By Capt. C. H. STIGAND, F.R.G.S. (*Seeley & Co., Ltd.*, 16s. net).

The Colonial Office List map of British East Africa contains a warning that the boundary with Abyssinia has not been delimited, and though the task of delimitation has, since the publication of that map, been carried out by Major Gwynn and his colleagues, the country remains to a large extent a *terra incognita*. Abyssinia is a mountainous country surrounded by waterless deserts. It can only be entered at a few places and then by narrow and precipitous tracks cut along the mountain sides. Between this country and the highlands of British East Africa lies a desolate and waterless region, for the most part uninhabited and uninhabitable. It is impossible for our colony to expand in this direction, and the development of the future will lie to the fertile and populous regions westward. But for the explorer who wishes to break new ground the territory affords excellent opportunities, and Capt. Stigand used them by taking a route which no other European has trodden. He traversed a rocky and waterless country infested with a low bush with diabolical thorns, but he came across a good deal of grassy plain and abundance of game. An ominous piece of news is that a new illness has just appeared on the Omo river, which from the description appears to be sleeping sickness. If so, the tribe of the locality will probably be exterminated. Capt. Stigand thinks that the insect must have come from the swamps of the Nile, as it is now infecting the upper waters of the river.

The chief interest of the book lies in its description of the ideas of the natives. Capt. Stigand evidently spared no pains to understand their ways of thinking, and got on remarkably well with them throughout.

---

**Dry Farming in America :** A report by Mr. W. Macdonald, presented to the Transvaal Government. (*Printing Office, Pretoria*).

This report contains an account of a tour undertaken with the object of studying the system and results of Dry-farming in America. The conclusion is clear that it is profitable and has taken a firm hold.

Deep ploughing and frequent harrowing make a mellow earth which yields excellent crops, while if left hard and dry it would produce nothing. A power engine, steam or gasoline, is practically necessary to plough the land deeply, and government co-operation would greatly assist matters in this respect. The cultivation of the dry lands of South Africa and Australia on this method will eventually make an enormous difference in land settlement.

---

**"Travel and Exploration" (January).**

A composite article, to which Sir H. Johnston is one of the contributors, discusses outfit and equipment, in particular tents, beds, mosquito nets and medicines. It is pointed out that though green canvas is more expensive than white, it is preferable because it resists rot, owing to the sulphate of copper which it contains, and termites. The object of outfitters for travellers is to make one article serve more than one purpose, and a good deal of ingenuity is shown in the endeavour; but it seems to be carrying a good idea to excess when a mattress is devised which, on occasion, can be used as a raft. More likely to be of use is the japanned steel bath, fitted with a wicker lining and a lid so that it can be used as a portmanteau. Such an article has also been used in Nigeria as a shield against poisoned arrows. Pith helmets and putties are condemned, and on what seem good grounds. If a helmet is used, care should be taken to order the type which gives protection to the neck from the sun.

---

**"Science Progress" (No. 15. *John Murray*; 5s. net).**

An article on "Palæolithic Races and their Modern Representatives" sums up the finds of prehistoric man. Till recently the Gibraltar skull was the best example of the Neandertal man, but with this exception our colonies have still to contribute to these interesting discoveries. Mr. Parkin gives an excellent account of Para-rubber cultivation, in which his Ceylon experience figures largely. Recent scientific works are reviewed by well-known authorities. An article on Halley's Comet attributes the victory of William the Conqueror at Hastings to its opportune appearance in 1066, and very pertinently enquires "What language can convey the full significance of this conclusion?" It is a relief at any rate to find that the writer does not attach the same fell significance to the Comet's reappearance in 1910.

---

A list of Colonial Laws dealing with Patents, Designs, Trade Marks and the Marking of Merchandise, and Regulations issued thereunder, has been published in the *Miscellaneous Series of Colonial Reports*. (No. 70, Cd. 4,996, price 1d.)

## COLONIAL STAMPS.

REGISTRATION ENVELOPES.—It may be of interest to note the advantage of indicating by means of one stamp the fact that postage has been paid as well as Registration fee.

The cost of a new embossing die where a Registration die already exists is somewhat prohibitive, but when a new one is being ordered the combined stamp, as used by the Imperial Government, can be adopted without extra expense.

Another way of producing a combined stamp at a nominal cost is by means of an electrotype obtained from the King's head postcard die, as in the case of Gold Coast.

It is worthy of note that it is impossible to produce a satisfactory electrotype for printing a combined stamp from a postage stamp die owing to the wording which appears thereon and which would cause confusion.

A few Colonies have not yet adopted the newer form of Registration Envelope, the flap of which fastens in front. This is particularly suitable where a combined stamp is used. Such an envelope has the advantage of displaying all the evidence of prepayment on one side, and the change can be made without expense.

BERMUDA is about to celebrate the tercentenary of the Colony's Establishment by a completely new issue of stamps of a design which will, we think, be of a much more artistic character than the existing issue. The first value to be sent out is the  $\frac{1}{2}$ d., which will be immediately followed by the 1d., 6d. and 1/- values. No order has been received for the other values, which will be  $\frac{1}{4}$ d., 2d.,  $2\frac{1}{2}$ d., 3d. and 4d.

The design will show in an upright oval a 17th century ship in full sail, with the Cross of St. George at each masthead, similar to that which was used on the reverse of the piece known as Hogmoney, described and depicted on page 101, Vol. I., of Sir J. H. Lefroy's "Memorials of the Bermudas."

Hogmoney, it is interesting to note, was the earliest attempt at introduction of currency in Bermuda. It was a brass token for payment to labourers, and exchangeable for provisions, etc., to the value in pence indicated on the face at the store of the Chartered

Company. The coin was never popular, tobacco being preferred as a medium of exchange.

The new stamps will permanently supersede the existing "Arms" issue, and will be printed in single colours by the steel plate process, the new colour scheme described in our last issue being followed.

CEYLON.—A very extensive alteration will shortly be made in the stamps issued by the Colony. Separate telegraph and foreign bill stamps are to be abolished, and postage stamps will be used in their place. This entails a revision of the values represented in the series of postage stamps. Six new denominations will be introduced, *i.e.*, 10 cents, 50 cents, Rs. 1, Rs. 2 and Rs. 10, and five denominations for which there is a comparatively small demand will be abolished, *i.e.*, 4 cents, 12 cents, 75 cents, Rs. 1.50 and Rs. 2.25. This will leave thirteen denominations of postage stamps which will be used for all postal and telegraph purposes, and for the purpose of foreign bill stamps; of the above stamps new plates will be provided for the existing 2 cents, 5 cents and 6 cents stamps, and for the six new denominations referred to above. The 3 cents, 10 cents, 15 cents, 25 cents, 30 cents, 50 cents, and Rs. 1 stamps will be printed in sheets of 240, the 5 cents stamps in sheets of 480, and the remaining values in sheets of 120 stamps.

The colours of the stamps other than the 3 cents, 6 cents and 15 cents stamps, which will be in the Postal Union colours, will be as follows, and the figures of value will be in colour on a plain ground.

Value.	Key Plate.	Duty.	Paper.
2 cents	... Orange.	Orange.	White.
5 "	... Purple.	Purple.	"
10 "	... Sage Green.	Purple.	"
25 "	... Grey.	Grey.	"
30 "	... Blue Purple.	Green.	"
50 "	... Brown.	Brown.	"
Rs. 1	... Purple.	Purple.	Yellow.
2	... Red.	Red.	"
5	... Black.	Black.	Green.
10	... Black.	Black.	Red.

The paper will be unsurfaced with the possible exception of the 5 cents value.

FEDERATED MALAY STATES.—The State of Trengganu, which passed under British Protection in July, 1909, is on the point of making an issue of stamps bearing the Sultan's portrait in the centre. The values will be 1, 3, 4, 5, 8, 10, 20 and 50 cents, and \$1.

FIG. 1.—2½d. and 6d. stamps in the new single colours are now on order.

## RECENT TRANSFERS AND PROMOTIONS MADE BY THE SECRETARY OF STATE.

- Major J. A. BURDON, C.M.G.** (First Class Resident, Northern Nigeria), Colonial Secretary, Barbados.
- Mr. GEORGE SMITH** (Registrar-General, Cyprus), Colonial Secretary, Mauritius.
- Captain C. H. ARMITAGE, D.S.O.** (Provincial Commissioner, Ashanti), Chief Commissioner, Northern Territories, Gold Coast.
- Mr. R. T. ORPEN** (Police Magistrate, Southern Nigeria), Resident Magistrate, Jamaica.
- Captain A. M. FLEURY** (District Commissioner, Gold Coast), Local Commandant of Police, Cyprus.
- Mr. H. F. PICKWOOD** (late District Superintendent of Police, Northern Nigeria), Out-Island Commissioner, Bahamas.
- Lieutenant G. A. E. POOLE** (Gold Coast Regiment, West African Frontier Force), Assistant District Commissioner, Gold Coast.
- Lieutenant H. B. POPHAM** (Gold Coast Regiment, West African Frontier Force), Junior Assistant Colonial Secretary, Gold Coast.
- Captain G. C. CORRY-SMITH** (2nd Battalion, Southern Nigeria Regiment, West African Frontier Force), Assistant District Commissioner, Southern Nigeria.
- Lieutenant R. M. BLACKWOOD** (2nd Battalion, Northern Nigeria Regiment, West African Frontier Force), Assistant Resident, Northern Nigeria.

- Mr. J. H. DUFF (Assistant Master, Bo School, Sierra Leone),  
Inspector of Schools, Jamaica.
- Mr. W. A. FLACKE (Second Class Postmaster, East Africa Protectorate),  
Provincial Postmaster, Southern Nigeria.
- Mr. H. J. HARRIS (Postmaster, Fort Jameson, North-Eastern Rhodesia),  
Provincial Postmaster, Southern Nigeria.
- Mr. G. P. LEWIS (Postmaster in the East Africa Protectorate),  
Assistant Postmaster-General, Northern Nigeria.
- Mr. G. F. MASON (Third Class Clerk, Treasury, British Guiana),  
Assistant Postmaster-General, Northern Nigeria.
- Mr. H. D. BRASSINGTON (Fourth Class Clerk, Treasury, British Guiana),  
Financial Assistant (Second Grade), Southern Nigeria.
- Mr. G. A. TENGELY (Fifth Class Clerk, Customs, British Guiana)  
Supervisor of Customs (Second Grade), Southern Nigeria.
- Mr. J. ALEXANDER (retrenched from the Transvaal Civil Service),  
Assistant Accountant, Marine Department, Southern Nigeria.

**OFFICIALS ON LEAVE OF ABSENCE  
IN THIS COUNTRY WITH DATE OF  
EXPIRATION OF LEAVE.**

This List is compiled from the Leave Certificates sent to the Crown Agents for the Colonies. The Editors will be glad to receive notice of any other cases of Colonial Officials on Long Leave.

# MERRYWEATHERS' PATENT "Greenwich Gem" Steam Fire Engine.

THE LIGHTEST AND BEST STEAM FIRE ENGINE ON THE MARKET.

## ADVANTAGES.

Fire Door and Machinery at rear.

—+—  
Accessibility of Valves.

—+—  
Simplicity of Machinery.

—+—  
No Steam Pipes to cause trouble.

A FIRE BRIGADE CHIEF writes:—

"The 'Gem' is so compact and handy that it can easily be stoked and worked by one man—a fact that does not apply to other Fire Engines."

—+—  
*Adopted by London and other Fire Brigades all over the World.*

—+—  
**MAKERS OF EVERY DESCRIPTION OF MOTOR FIRE APPARATUS.**

—+—  
**MERRYWEATHERS' "London Made" DUB-SUB CANYAS HOSE,** woven on Improved Looms at Greenwich Road Works. It is capable of standing great pressure, and is therefore suitable for the most powerful Steam Fire Engines and Pumps.

—+—  
*WRITE FOR CATALOGUES AND LISTS.*

—+—  
**MERRYWEATHER & SONS** Ld.  
**63, LONG ACRE, W.C.; & WORKS, GREENWICH, S.E.,**  
**LONDON.**

ESTABLISHED OVER 200 YEARS.

# HUGO GRIEBERT & CO.,

Dealers in Rare Postage Stamps.

IMPORTERS OF UNUSED AND

Goods value £20 and upwards will be sent carriage free to any port.

## OPINIONS OF THE PRESS.

"**Truth**" says—"Our latest discovery in Tailoring is Evans & Co., who can actually fit."

"**Field**" says—"It is with some degree of confidence that we can recommend the breeches made by Evans & Co."

"Any and every tailor will attempt breeches making, but the real artists are few and far between. Mr. Evans has made a study of breeches for many years, and takes an extraordinary amount of pains about fitting, and he has certainly solved the problem of how breeches should be made. Tightness at the knee combined with great comfort all over are very strong points with these breeches, and the cut is absolutely correct."

We have received thousands of **TESTIMONIALS** from all parts of the world from which we quote the following:—

"Hartbeestfontein, Transvaal.

"Gentlemen,—Breeches ordered arrived safely, and both as regards cut and fit leave nothing to be desired. It is interesting to note that some breeches I ordered at the same time from a well-known house (giving the same measurements) fitted me like ready-made slops. I did not think it possible for you to give such a good fit from self-measurements, and any other orders which I may require I shall certainly place with your firm.

"Yours truly, O.N.B."

When sending for patterns, state kind & colour preferred.

# MERRYWEATHERS' LONDON-MADE "DUB-SUB" CANVAS HOSE

WOVEN AT

Merryweather & Sons' Works, Greenwich Road, London, S.E.

In order to meet the demand for a

## SPECIALLY STRONG CANVAS HOSE,

necessitated by the more general use of Steam Fire Engines and High-pressure Hydrants, Messrs. Merryweather & Sons have introduced their "Dub-Sub" (Double Substance) Canvas Hose.

This Hose is made of specially selected long flax of the very highest quality, and woven on greatly improved looms, which enable a hose of great strength to be manufactured, and with 15 strands instead of the 9 or 10 usually employed, and each individual thread is extra stout and strong. It is

## CAPABLE OF STANDING GREAT PRESSURE,

therefore suitable for the most powerful Steam Fire Engines and Pumps. It represents the very

## LATEST & BEST PRACTICE IN WEAVING CANVAS FIRE HOSE.

The special stoutness of this Hose ensures for it a very much longer life than that of ordinary Canvas Hose, as it is much better adapted to withstand the effects of the chafing and rubbing unavoidable in course of ordinary work.

The "Dub-Sub" (Double Substance) Hose, when first used, allows the water to pass through the pores somewhat freely, but after it has been in use a short time it becomes as tight as more finely woven hose.

## MERRYWEATHERS' INDIA-RUBBER-LINED "DUB-SUB" HOSE

Is a Watertight Hose of the Very Highest Class.

*CAUTION—See that the name "MERRYWEATHERS," the brand, appear on every length.*

Indent for MERRYWEATHER HOSE.

**MERRYWEATHER & SONS,**

 Goods value £20 and upwards will be sent carriage free to any port.

### OPINIONS OF THE PRESS.

"**Truth**" says:—"Our latest discovery in Tailoring is Evans & Co., who can actually fit."

"**Field**" says:—"It is with some degree of confidence that we can recommend the breeches made by Evans & Co."

"Any and every tailor will attempt breeches making, but the real artists are few and far between. Mr. Evans has made a study of breeches for many years, and takes an extraordinary amount of pains about fitting, and he has certainly solved the problem of how breeches should be made. Tightness at the knee combined with great comfort all over are very strong points with these breeches, and the cut is absolutely correct."

We have received thousands of **TESTIMONIALS** from all parts of the world from which we quote the following:—

"Hartbeestfontein, Transvaal.

"Gentlemen,—Breeches ordered arrived safely, and both as regards cut and fit leave nothing to be desired. It is interesting to note that some breeches I ordered at the same time from a well-known house (giving the same measurements) fitted me like ready-made slops. I did not think it possible for you to give such a good fit from self-measurements, and any other orders which I may require I shall certainly place with your firm.

"Yours truly, C.N.B."

When sending for patterns, state kind & colour preferred.

British and African Steam Navigation Co., Ltd., and African Steamship Co.

### EXCELLENT ACCOMMODATION

with all Modern Conveniences, Hot and Cold Baths, Electric Light and Bells, is provided for passengers. The express service Steamers are also fitted with refrigerating chambers, ensuring a constant supply of fresh meat, vegetables, &c., all through the voyage.

---

#### The Imperial Direct West India Mail Service Co., Ltd.

maintain a regular fortnightly service (under Contract with His Majesty's Government) between Avonmouth, Bristol and Jamaica (Kingston).

To Bermuda outwards there is also a regular service every six weeks by the R.M.S. "Port Kingston."

These Steamers have been specially built for the service and have magnificent accommodation for First and Second-Class Passengers at moderate rates.

---

THE LARGE MODERN HOTEL "CONSTANT SPRING" provides excellent accommodation at reasonable rates.

The Island of Jamaica possesses great natural beauty, and its warm healthy climate is recommended by the medical faculty. Polo-playing, Yachting, Golf Tennis, Riding and Driving, are particularly good, and there is excellent Shooting and Fishing.

# PURE MILK & EGG POWDER

(TRUFOOD PROCESS).

100% soluble in cold water, and will not separate in solution.  
Made in Cheshire from Pure Milk from Inspected Dairies.  
Double the efficiency of any other Milk Powder.

*"The Lancet"* says:—"We regard all these preparations with distinct favour; they are an obvious advance on food preparations dried by the agency of heat above coagulating point."

Extract from *"Army & Navy Register,"* Washington, D.C., June 27, '08. Referring to above products, says—"Further reports received from the Atlantic Fleet indicate great satisfaction with the powdered egg which was added to the list of preserved provisions furnished to the Fleet on its departure from Hampton Roads. **The article has met a real need, and has established itself as a permanent article of diet.**"

Ex-President Roosevelt took a large supply of Trumilk and Truegg with him on his hunting expedition to Africa.

*We would call special attention of Army and Navy Officers, Yachtsmen, and others, to the above products, which always give the greatest satisfaction.*

# MERRYWEATHERS' PATENT "Greenwich Gem" Steam Fire Engine.

THE LIGHTEST AND BEST STEAM FIRE ENGINE ON THE MARKET.

## ADVANTAGES.

Fire Door and Machinery at rear.

—  
Accessibility of Valves.

—  
Simplicity of Machinery.

—  
No Steam Pipes to cause trouble.

A FIRE BRIGADE CHIEF writes:—

"The 'Gem' is so compact and handy that it can easily be stoked and worked by one man—a fact that does not apply to other Fire Engines."

—

 Goods value £20 and upwards will be sent carriage free to any port.

**OPINIONS OF THE PRESS.**

"**Truth**" says:—"Our latest discovery in Tailoring is Evans & Co., who can actually fit."

"**Field**" says:—"It is with some degree of confidence that we can recommend the breeches made by Evans & Co."

"Any and every tailor will attempt breeches making, but the real artists are few and far between. Mr. Evans has made a study of breeches for many years, and takes an extraordinary amount of pains about fitting, and he has certainly solved the problem of how breeches should be made. Tightness at the knee combined with great comfort all over are very strong points with these breeches, and the cut is absolutely correct."

We have received thousands of **TESTIMONIALS** from all parts of the world from which we quote the following:—

"Hartbeestfontein, Transvaal.

"Gentlemen,—Breeches ordered arrived safely, and both as regards cut and fit leave nothing to be desired. It is interesting to note that some breeches I ordered at the same time from a well-known house (giving the same measurements) fitted me like ready-made slops. I did not think it possible for you to give such a good fit from self-measurements, and any other orders which I may require I shall certainly place with your firm.

"Yours truly, C.N.B."

# "HANDBOOK OF THE BRITISH COLONIAL EMPIRE."

BY

**W. H. MERCER, C.M.G.,**

*One of the Crown Agents for the Colonies ;*

AND

**A. J. HARDING,**

*Of the Colonial Office.*

---

"Whilst the 'Colonial Office List' is issued mainly for the use of the official world, the present volume is intended primarily for educational purposes and for the use of those desiring succinct and reliable information regarding the history, trade, government, and commercial development of the various outlying portions of the Empire. A large amount of useful information upon those subjects has been gathered together by the Authors, who, owing to their official positions in the Colonial Civil Service, have had exceptional opportunities for obtaining the latest and most authentic details regarding the present administrative and commercial state of all parts of the Empire. The book is well suited for educational purposes, and might with advantage be introduced not only into the schools of the United Kingdom, but adopted by Colonial educational institutions in order that students in any single portion of the Empire may know something of the history, character, and condition of all its widely scattered parts."

*Journal of the Royal Colonial Institute.*

\* \* \* \* \*

"The book is intended for educational purposes and is so attractively written, and contains such a fund of information, that it cannot fail to become popular."

*Education.*

# BENSON'S

## "EMPIRE" PLATE

SPoons, FORKS & TABLE CUTLERY,  
BREAKFAST, DINNER AND TEA SETS,  
AND OTHER HOUSEHOLD WARE.

"EMPIRE" PLATE is treble plated on pure Nickel Silver. The patterns are reproductions from fine old Silver modes, and have all the beauty of line and form of the Silver of 150 years ago; apart from the Hall Mark no difference is visible.

At the 1862 Exhibition, "Empire" Plate was awarded Prize Medals for Excellence of Manufacture, and it still retains that pre-eminence for which it was noted fifty years ago, whilst the prices are, quality considered, strictly moderate, either for Cash, or on "The Times" System of Monthly Payments.

"THE VILLA" Solid Oak Case, with Lift-out Trays, containing 110 pieces of "Empire" Plate and Sheffield Cutlery.

A Service for 12 persons £12 10s. to £21.  
(Others £3 to £100.)

PRICE  
LISTS  
FREE.

No. 1, of Watches, Chains and Jewellery.  
No. 2, of Clocks, "Empire" Plate, Cutlery, and Silver Articles for Presents.

Mention "Colonial Office Journal."

## 62 & 64, LUDGATE HILL, E.C.

# PURE MILK & EGG POWDER

(TRUFOOD PROCESS).

100% soluble in cold water, and will not separate in solution.

Made in Cheshire from Pure Milk from Inspected Dairies.

Double the efficiency of any other Milk Powder.

"The Lancet" says:—"We regard all these preparations with distinct favour; they are an obvious advance on food preparations dried by the agency of heat above coagulating point."

Extract from "Army & Navy Register," Washington, D.C., June 27, '08. Referring to above products, says—"Further reports received from the Atlantic Fleet indicate great satisfaction with the powdered egg which was added to the list of preserved provisions furnished to the Fleet on its departure from Hampton Roads. The article has met a real need, and has established itself as a permanent article of diet."

Ex-President Roosevelt took a large supply of Trumilk and Truegg with him on his hunting expedition to Africa.

**We would call special attention of Army and Navy Officers, Yachtsmen, and others, to the above products, which always give the greatest satisfaction.**

## UTILITY MOTORS

### NOTICE

*(Scotstoun, Glasgow, 1st January, 1910).*

We beg to intimate that the Lacre Motor Car Coy. Ltd., London, have ceased to be our concessionaires for England and Wales.

#### **Special features for Colonies:**

**Extra Ground Clearance.**

**Large Petrol Tanks.**

**Special Cooling Arrangement.**

**Faransure Tyres.**

**Detachable Steel Flanges.**

Albion Motor Vehicles still occupy the premier position for Simplicity and Reliability. Our experimental work was all done years ago, and we claim to be the largest manufacturers of Motor Vans, Lorries, Char-a-bancs, etc., with a capacity up to 2 ton load, of any Firm in Europe.

We strongly recommend the fitting of Faransure Tyres where the Vehicles are for use abroad, owing to the ease with which new rubbers can be fixed by the driver without any assistance.

ALBION MOTOR  
CAR CO., LTD.,  
Scotstoun, GLASGOW.

London Depot:

 Approximate cost of carriage (parcel post) per suit of clothes to the Colonies, and other countries, &c. (which must be added to cost of suit):—Canada, 5s.; Cape Colony, 7s.; Transvaal and Orange River Colony, 8s.; Rhodesia, 15s. 9d.; Nigeria, Gold Coast, West Indies, Ceylon, Hong Kong, Cyprus, Egypt, Malta, Falkland Islands, Gambia, Gibraltar, India, 3s.; Australia, 5s.; New Zealand, Brazil, 8s.; Chili, 4s.; Mexico, 3s. 8d.; Argentine Republic, 4s. 10d.  
 Goods value £20 and upwards will be sent carriage free to any port.

## OPINIONS OF THE PRESS.

"**Truth**" says:—"Our latest discovery in Tailoring is Evans & Co., who can actually fit."  
 "**Field**" says:—"It is with some degree of confidence that we can recommend the breeches made by Evans & Co."  
 "Any and every tailor will attempt breeches making, but the real artists are few and far between. Mr. Evans has made a study of breeches for many years, and takes an extraordinary amount of pains about fitting, and he has certainly solved the problem of how breeches should be made. Tightness at the knee combined with great comfort all over are very strong points with these breeches, and the cut is absolutely correct."

We have received thousands of **TESTIMONIALS** from all parts of the world from which we quote the following:—

"Hartebeestfontein, Transvaal.  
 "Gentlemen,—Breeches ordered arrived safely, and both as regards cut and fit leave nothing to be desired. It is interesting to note that some breeches I ordered at the same time from a well-known house (giving the same measurements) fitted me like ready-made slops. I did not think it possible for you to give such a good fit from self-measurements, and any other orders which I may require I shall certainly place with your firm.

"Yours truly, O.N.B."

When sending for patterns, state kind & colour preferred.

maintain a regular fortnightly service (under Contract with His Majesty's Government) between Avonmouth, Bristol and Jamaica (Kingston).

To and from Bermuda there is also a regular service every six weeks by the R.M.S. "Port Kingston."

These Steamers have been specially built for the service and have magnificent accommodation for First and Second-Class Passengers at moderate rates.

---

THE LARGE MODERN HOTEL "CONSTANT SPRING" provides excellent accommodation at reasonable rates.

The Island of Jamaica possesses great natural beauty, and its warm healthy climate is recommended by the medical faculty. Polo-playing, Yachting, Golf Tennis, Riding and Driving, are particularly good, and there is excellent Shooting and Fishing.

ADVERTISEMENTS.

# BENSON'S

"THE VILLA" Solid Oak Case, with Lift-out Tray, containing 110 pieces of "Empire" Plate and Sheffield Cutlery.

A Service for 12 persons £12 10s. to £21.  
(Others £3 to £100.)

## "EMPIRE" & STERLING SILVER PLATE

SPOONS, FORKS, TABLE CUTLERY, AND OTHER HOUSEHOLD WARE.

"EMPIRE" PLATE is treble plated on pure Nickel Silver. The patterns are reproductions from fine old Silver models, and have all the beauty of line and form of the Silver of 150 years ago; apart from the Hall Mark no difference is visible.

At the 1862 Exhibition, "Empire" Plate was awarded Prize Medals for Excellence of Manufacture, and it still retains that pre-eminence for which it was noted fifty years ago, whilst the prices are, quality considered, strictly moderate, either for Cash, or on "The Times" System of Monthly Payments.

PRICE  
LISTS  
FREE.

No. 1, of Watches, Chains and Jewellery.  
No. 2, of Clocks, "Empire" Plate, Cutlery, and Silver Articles for Presents.

EDITORIAL NOTES.

THE result of the General Election in Australia has been to give the Labour Party a majority of ten in the Senate and of thirteen in the House of Assembly, and the change in the political situation thus brought about constitutes an event of first-rate importance. Mr. Deakin's resignation and Mr. Fisher's acceptance of office have followed as a matter of course. This is not the first occasion when a Labour Ministry has held office in the Commonwealth. Mr. Fisher was Prime Minister from November, 1908, to June, 1909, and Mr. J. C. Watson held office as head of a Labour Cabinet for four months in 1904; but on each of these occasions, not only was the Government's tenure of office very brief, but it was dependent on the sufferance of other parties. Neither Mr. Watson nor Mr. Fisher has on any previous occasion been the head of a party constituting an absolute majority of both Houses. Australia, ever since the attainment of federation, has been habituated to the three-party system, and it would hardly be an exaggeration to say that under the working of that system the Labour Party has found itself able to exercise more influence on the course of legislation in opposition than in office. When Mr. Deakin joined forces with Mr. Cook a year ago to form the Fusion party, the Commonwealth obtained its first experience of the two-party system, and of this there is now likely to be a continuance. In his "Notes on a Visit to Australia, New

Zealand and Fiji," recently issued as a White Paper, Sir Charles Lucas expressed the opinion "that the dividing line in politics everywhere tends more and more to be the line between labour and non-labour," and in Australia, at any rate, this division may now be regarded as an accomplished fact.

---

The political change in Australia is unlikely to lead to any great alteration in the relations between the Commonwealth and the Home Government. Mr. Fisher's policy during his previous brief term of office, and the programme upon which he invited the support of the Australian electors, show him to be a not less ardent Imperialist than Mr. Deakin, and upon such questions as the naval and military schemes of the Commonwealth there will be no serious discontinuity of policy. In the "Notes" to which we have referred above, Sir Charles Lucas remarks that "in these British communities, which are shaping into so many British nations, of the two main parties in the State—labour and non-labour—the latter contains, and under existing conditions is likely to contain, far more citizens with personal knowledge of the Mother Country than the former, for the simple reason that it contains more who have the means and leisure to travel. This I regard as a misfortune. It may mean, in days to come, that one party will be more closely in touch and sympathy with the Mother Country than the other, whereas everyone must wish that all should be a par in these respects." So far as the Commonwealth Labour Party can be said to labour under a disability in this respect—and we are not forgetting that at least one of Mr. Fisher's colleagues, Mr. W. M. Hughes, has been a fairly frequent visitor to this country—it will in all probability have an opportunity of removing it next year, when it may be anticipated that the leaders of the party will represent the Commonwealth at the Imperial Conference.

---

In the sphere of domestic policy the principal result of the elections appears likely to be an increase of the power of the Commonwealth at the expense of the States. Most observers have long anticipated a development of this nature in Australian politics. Parts of the industrial policy of the Commonwealth to which the Labour Party attached peculiar importance have been rendered ineffective by decisions of the Supreme Court as to the limitations of the constitutional powers of the Federal Government, and until those decisions have been set aside by formal amendments to the constitution, it is hardly possible for the policy of standardising industrial conditions throughout the Commonwealth, and setting up a "national minimum" in the matters of wages, hours and conditions of employment to which all industries must conform, to be carried into effect. Both parties aimed at an extension of the power of the

Commonwealth, but the Labour Party are prepared to seek the attainment of their ends by more summary and decisive means than were their opponents. They should be able to carry out their policy, as they appear to be in a position of greater strength than any previous Commonwealth Government.

---

Concurrently with the General Election proposals for two amendments of the Commonwealth Constitution were submitted to a referendum of the electors. The first proposal, which has been adopted, was to empower the Commonwealth to take over the whole of the State debts, and not merely such debts as existed at the date of the establishment of the Commonwealth. The second proposal was for a settlement of the vexed question of the financial relations between the Commonwealth and the States upon the lines agreed upon at the Conference held last year between the Commonwealth and States Governments. Each State was to receive from the Commonwealth an annual sum equivalent to twenty-five shillings per head of its population, Western Australia receiving in addition a special payment of £250,000, diminishing annually by £10,000, one half of this special payment being made up by contributions from the other States proportionate to their population. The new arrangement was to date from July 1st, 1910, and for the year 1909-10 the Commonwealth was to be entitled to retain £600,000 in addition to the quarter of the net revenue from Customs and Excise to which it is entitled under the "Braddon Clause." The Labour Party opposed this proposal, objecting to the embodiment in the Constitution of an arrangement which they regarded as unduly generous to the States, and, as was natural in view of the result of the election, it has been rejected by the electors. From the new Government the States are not likely to obtain equally favourable terms.

---

The Annual Report of the Emigrants' Information Office contains some interesting remarks on the Chairman's visit to Canada last year. He reports that he was able to satisfy himself that the literature which the office issues corresponded very closely to the actual conditions of the Dominion. He found that Canadians are generally convinced of the necessity of maintaining the provisions of the Immigration Law relating to the restrictions imposed on certain classes of immigrants and the power of deportation, and he came to the conclusion that the actual effect of these provisions has been to improve the quality of emigrants from the United Kingdom to Canada. He formed a very favourable view as to the prospects of the policy of child emigration, and found a general desire in Canada for its further extension. An interesting passage in the report deals with the alleged inadaptability of the English emigrant to Canadian contingents.

“From the many conversations which he had with people, both officials and others, in a position to form an opinion, the Chairman could not resist the conclusion that the feeling is prevalent in Canada that many of the emigrants from England are not readily successful in conforming to the requirements of their new country, and that in this respect they fall short of emigrants from the United States, and even of emigrants from some Continental countries. The fault alleged would seem to be mainly one of temperament, and may, so far as it is possible to summarise in one phrase an opinion widely held and variously expressed, be said to consist in a lack of adaptability. No one would be found to assert that this is common to all English immigrants. On the contrary, it was generally admitted that it was the fault of a minority, though no doubt the majority found greater initial difficulties in consequence. The best English immigrant was spoken of in terms of the highest praise. If the sentiment described, which must be a handicap to a great many deserving English emigrants, is to be successfully combated, the Committee are of opinion that the practice of sending to the Dominion those who have been social failures in this country, or who are otherwise undesirable or unfitted to take up hard work in a new country, cannot be too strongly deprecated.”

In connection with the warnings which the office from time to time finds it necessary to issue, some remarkable particulars are given of a case in which a number of Scottish working-men were induced to emigrate to South and Central America, and had ultimately to be repatriated at the expense of the Foreign Office. In this connection it may be noticed that, in reply to questions in the House of Commons, Colonel Seely pointed out that the practical result of the work of the office is to direct the stream of emigration from the United Kingdom to British Possessions in preference to foreign countries to whose conditions the British emigrant is less suited.

---

With the commencement of the season for emigration, Canada has still further increased the severity of its regulations. In the case of a family entering Canada it is now necessary for the head of the family to have in his or her possession, in addition to the means of transport to their ultimate destination, a sum of \$25 for each person of the age of eighteen years or upwards, and a sum of \$12.50 for each person under that age. It is also intimated that in the case of persons assisted to emigrate by charitable societies, or out of public funds, the necessary approval of the Canadian Agency will only be given for persons who can be shown to be proceeding to farm work or to domestic service. This regulation, if strictly enforced, will very seriously limit the operations of emigration societies and distress committees, and attention has already been drawn to it in

Parliament and in the Press. Canada welcomes the genuine agricultural emigrant, but appears determined to exclude the town dweller, and those who look to emigration as a means of dealing with the problem of urban congestion at home would do well to realize the strength of her determination in this respect.

---

The Union of South Africa came into formal existence on May 31st, and, as had been anticipated, General Botha was invited by Viscount Gladstone to form the first Ministry, and accepted the task. Even those who would have liked to see Mr. Merriman crown his long period of public service in South Africa by attaining the position of first Union Premier, have recognized the peculiar fitness of the selection of General Botha. There could be no more striking evidence of the work of reconciliation which has been carried on since the close of the South African War eight years ago, and General Botha possesses the special and rare qualification of enjoying in an unusual degree the confidence of his opponents. It is understood that Mr. Merriman was invited to join the new Cabinet, but declined. It includes, however, the late Prime Ministers of the Orange Free State and Natal, and is admitted to be a strong combination. The Cape has four representatives in it, the Transvaal three and the other two Colonies each two. One of the first appointments made by the new Ministry was that of Sir Richard Solomon as the first High Commissioner of the Union in London. The cordial congratulations received from Canada and Australia were a pleasant feature of the inaugural celebrations.

---

The separation of the Crown Colonies and Dominions work of the Colonial Office has been marked by the issue of a new set of Parliamentary Papers bearing the title "Dominions." To the first of these, containing Sir Charles Lucas's notes on his tour of last year, allusion has already been made. The second contains a report on the Work of the Dominions Department for 1909-1910, which is intended to be the first of an annual series. The value of this report in bringing together the various matters of public interest connected with the self governing Dominions has met with general recognition. Various conferences, official and unofficial, are dealt with, and particulars of a number of international agreements affecting the Dominions are given. The progress of events in Canada and Newfoundland, Australia and New Zealand, and South Africa is briefly summarized, and an Appendix contains the most important legislative measures passed in the Dominions during the year under review.

---

An Australian Committee on the Press Cable Service has recommended the completion of the All Red Cable route by laying

down an Atlantic cable section and a Canadian land line, "the result of which would make possible a substantial reduction in charges for Press cables." The cause of the enquiry into the subject was the peculiar position of the Australian newspapers as regards news from the rest of the world. The leading papers have long formed an association, in conjunction with Reuter's Agency, which practically secures a monopoly of outside news, and naturally the smaller papers which are outside the combination are much dissatisfied. The Committee came to the conclusion that this position is detrimental to the public interest, because it:—

"(a) Makes it extremely difficult, if not absolutely impossible, for new and competing newspapers to obtain a cable service at a reasonable rate.

"(b) Gives an imperfect cable service and does not give sufficient news of the various parts of the Empire.

"(c) Retards, by its costliness, the spread of knowledge and world's news amongst the people.

"(d) Makes it difficult for the provincial press to establish or maintain an effective supply of cables, and thus tends to centralize power and influence in a few metropolitan journals."

It does not appear certain, however, that a reduction in the cost of cabling would break up the monopoly. Quite recently the price for messages was reduced by 3d per word, but the effect of this was merely to put about £367 a month into the pockets of the Association, without widening the range of publication, though some increase of cabled matter took place. It is difficult to see in what sense it is meant that a substantial reduction of charges could be made possible by the state ownership of Atlantic and Canadian lines. No estimate whatever is given of the cost of these undertakings or of the receipts, and presumably, therefore, all that is meant is that the government concerned would have the physical means of cabling Press messages at lower rates. Some much better case than this will have to be shown for a Government Atlantic cable. As regards Canada, the Pacific Cable Board have acquired the use of a line in order to prevent delays and inaccuracies, but they have of course to pay for it.

The report of the Congress of the Chambers of Commerce of the Empire at Sydney has been published, and it is pleasant to see the evidence of the hearty welcome which the delegates received in Australia. The principal subject discussed was, it need hardly be said, that of Imperial reciprocal preference, and a heavy majority declared in favour of the principle. It is impossible to read the proceedings without realising that this view was largely based in a desire, admirable in itself, for closer union, and in the colonies which possess protective tariffs and are continually re-adjusting them, it is a comparatively simple matter to lower some duties in exchange for

similar concessions. In this country it is not a question of such easy manipulation, but of the introduction of a new doctrine. The ideal of a self-contained, self-sufficient Empire is a highly attractive one, but it is clear that this ideal cannot be attained by a series of simple arithmetical adjustments. Thus Great Britain cannot consume more than about one-quarter of the wool produced in Australia, and as the production increases the disproportion must become greater, because other parts of the world must inevitably develop more than this old country. This fact is more or less generally true of Colonial products, which are mainly in the nature of raw materials and marketable everywhere. From India we take some £33,000,000 in value yearly, as against £86,000,000 taken by foreign countries. The commercial future of the colonies rests mainly with the large staple products, and of these Great Britain can only take, under any fiscal system, a comparatively limited and decreasing proportion. But whatever may be the merits of the general controversy—and on this we express no opinion—the strong support given to the movement by merchants is a fact which must be acknowledged. It seems, however, to rest not so much on any exact calculations as on the general principle that the stability of the Empire can only be secured by some economic combination. Whether trade can or should be dealt with by preferential arrangements is a controversial question outside our province, but so far as the feeling of friendship and harmony is concerned it is clearly open to doubt whether it can be made stronger by increased buying and selling. When we hear of the Australian States describing British Commercial agents as parasites on the industries of the dominion, or when we regard the ill-feeling which is constantly being created by visible importations from abroad, it is impossible to resist the conclusion that commercial intercourse is responsible for a good deal of popular ill-feeling. It is only human for workers everywhere to be disposed to resent the coming in from outside of goods which they are prepared to turn out themselves, and whatever increase or division of trade may be effected by commercial arrangements it does not by any means follow that the two parties love one another any the more. The combination of the Empire is a big fact which rests on intellectual and moral sympathies, rather difficult perhaps to analyse and set out exactly, but none the less real and strong. Trade questions have throughout our Colonial history been a source of trouble and quarrels, and it is not there that are to be found the influences which unite the masses of territory.

---

At the annual meeting of the Association of Chambers of Commerce of the United Kingdom in April, many references were made to Colonial trade, and it is gratifying to find abundant evidence of the general interest taken in the subject. A resolution was carried

for the formation of an Imperial Council of Commerce, the object being to form a body which could collect and disseminate information for the benefit of the whole Empire. Each Government, it was agreed, gave out information about its own affairs, but no one collects facts for the benefit of all parts. No doubt there is a wide field for such an organisation, but the practical difficulty seems to be that, outside a comparatively small number of special subjects which are adequately represented by political or technical organisations, the matters in which the dominions and colonies are keenly interested are more or less local. It will be interesting to see whether the new body can encourage a wider range of interest, and it will be entitled to great credit if it does.

---

Two questions were raised at the meeting which merit the general consideration which it is desired to develop. A resolution was carried in favour of the recommendations of the Minority Report of the Royal Commission on Shipping Rings that the Board of Trade should be free to recognise any association which in its judgment is of an adequately representative character, and to direct an inquiry with full powers where it appears that important public interests are affected by the action of shipping conferences. The conclusions of the Majority Report have been discussed in a previous issue, and were, we think, fairly based on the evidence; but the circumstances may at any time change in such a way as to render that evidence insufficient or misleading. There are in fact some indications now that the rebate system is used to establish higher rates in the United Kingdom than are allowed in foreign countries, and if such a mischievous discrimination is practised on a serious scale the re-opening of the whole question will be necessary.

---

Another resolution approved of the reservation of Crown Lands in Protectorates and Crown Colonies in return for any expenditure from the National Exchequer, and Northern Nigeria was particularly referred to. This seems a reasonable business proposition at first sight. Great railways have been built on the principle of adjacent lands being granted to the railway, so that the enterprise can itself reap some of the benefit which its country gives to the neighbouring territory, and contracts and concessions are often now made on this footing. But in such cases the land has been more or less unoccupied and unclaimed, and the Government has had a fair claim to treat it as belonging to the state. In Northern Nigeria, and generally in West Africa, this is not the case; substantially speaking, every piece of land has an owner. It is true that the Government can usually acquire by negotiation with the natives, any land up country for such a purpose without any particular expense; but it would be quite a different matter for it to take advantage of

its influence to obtain large blocks of surrounding land. Even if it did there would be little prospect of its being able to make use of them. In the vicinity, however, of settlements, where land has a residential value, the community of a railway has a considerable effect, and it is good policy for the Government to acquire land before this upward movement takes place.

---

Last year the United States secured about 60 per cent. of the imports of Canada, and now British firms will have to face not only this formidable competition but also Germany and France, both in better positions than before. The seven years' tariff war between Germany and the Dominion has come to an end, and from the 1st of March German goods, instead of paying a surtax of  $33\frac{1}{2}$  per cent., came in under the General Tariff. The French treaty admits a long list of articles under the Intermediate Tariff. Under these circumstances British manufacturers are being strongly urged in the press to make determined efforts to keep and improve their position, and much good advice is being tendered to them, mostly to the effect that they should study Canadian requirements on the spot, and make exactly what is wanted. Probably the most has been made of the exceptional cases where the British manufacturer has insisted on supplying what he thinks is suitable rather than what the customer is used to. He is perfectly justified in not altering his machinery and the methods of his work-people for small and casual orders, and it is unreasonable to expect him to provide everything for everybody. But where a large and growing market is in existence it is well worth while to study its requirements and to hunt up business. In the case of Canada there is now a vast new market every year, and therefore every inducement to compete for custom. It is often good policy to employ a Canadian as an agent, with a liberal authority to advertise. The Boards of Trade of the various towns will help if applied to.

---

The Australian conference on radio-telegraphy point out in their report that, if high-power stations were erected at Sydney and at Doubtless Bay in New Zealand (1,200 miles east of Sydney), Fiji, 1,750 miles north-east of Sydney and 1,100 miles north of Doubtless Bay, would constitute the third point in a system of stations which, with a high-power station at Ocean Island, would form the bold outline and foundation of a Pacific scheme of wireless telegraphy capable of expansion and development into a more extensive scheme, which would constitute a network of inter-communication well worthy of the important Imperial interests involved.

Fiji is already connected with both Australia and New Zealand by the Pacific cable, and it is not essential that this cable service should be supplemental by radio-telegraphic stations. New Zealand

has, however, decided to erect at or near Doubtless Bay a high-power station, with a range of 1,250 miles, which would reach Sydney and Fiji.

The bulk of the carrying trade of the Pacific Islands is in the hands of companies whose headquarters are in Australia and New Zealand, but it is attended with no little difficulty, and much more business might be done if communication were better. Capitalists naturally hesitate to put money into enterprises in places difficult of access, and where it is necessary to put a great amount of trust in agents whom it is impossible to supervise. Disputes have frequently occurred, sometimes involving diplomatic negotiations, which it was impossible to settle satisfactorily owing to the slow and uncertain communication.

In addition to the above four high-power stations, it is proposed to have medium-power stations at the Solomons and the New Hebrides. The cost of the stations at Sydney and Doubtless Bay will be borne by Australia and New Zealand. The total cost of the other stations—Fiji, Ocean Island, Solomons and New Hebrides—is estimated at £42,000, of which it is proposed that the Imperial Government shall pay £23,344, New Zealand £2,333, Fiji £3,500, and Australia £12,833. It is further estimated that a continuous service would cost £13,820 a year, which it is proposed should be similarly apportioned.

No estimate is given of the revenue, but there can be no doubt that the traffic would be much too small to pay. The claims of the project, so far as the Imperial Government is concerned, rest mainly on its benefits for purposes of defence and administration.

---

The correspondence relating to the constitution of the Ceylon Legislative Council (Cd. 5,098) may be read with interest in all the Crown Colonies where there is a more or less popular demand for elective institutions. There is, no doubt, a strong movement among the educated natives of Ceylon in favour of the elective principle, and no dissatisfaction need be felt on this account; on the contrary it is a healthy symptom, testifying as it does both to the growth of education and to the increase of interest in public affairs. In such places the Government must have unofficial members in the Legislative Council, and if the community is prepared to express its wishes by elections there are clear advantages in this method over that of nomination. The difficulty in Ceylon is that the population consists of a number of different races, differing largely in customs and ideas, and it is therefore necessary, in order to secure fair representation, that the different communities should have their own members; thus, there are at present nominated members for the Mercantile, Planting, General European, Burgher, Low-country Sinhalese, Kandyan, Tamil, and Mohammedan communities. Now, whatever may be the

intellectual acquirements of the educated classes, the great mass of the rest is inarticulate, illiterate and incompetent to form political opinions. The best representation for these classes is given by the nominations of members to represent the different races. This, however, does not apply to the European and Burgher communities, and in these cases the Secretary of State has decided that the system of elections should be introduced.

---

The Supreme Court of Natal has settled (to some extent) a curious case which arose out of the shipwreck of the "Newark Castle" on the Zululand coast. This vessel carried several packages of rupee notes which had been made in England for the Mauritius Government, and these notes were complete, *i.e.*, the signatures had been printed. It will be readily realised that no little apprehension was felt when the news came that the ship had gone ashore at an out of the way place, for it is notorious that when negotiable paper miscarries the "innocent" holder for value usually turns up in due course. It is true that the notes had legally no currency value without a warrant for issue made by the Mauritius Government. But as they were complete in the face of them, the honest purchaser might put forward a plausible grievance. Fortunately the bulk of the issues was secured by the Natal Customs officials on the spot. Thereupon they were sued by a plaintiff whose case rested on the fact that he had bought the wrecked steamer with its contents, from the shipowners. But the Court held that this sale was invalid. The owners, under both English and the Colonial law, could make a good sale under such circumstances if there was urgent necessity for it and if communication with the cargo owner was impracticable. In this case no attempt was made to inform the cargo owners, though this might easily have been done, and therefore they could not give the purchaser a good title; nor was there any necessity for the sale, as the articles were no longer in peril. The judgment does not touch the notes which were picked up by other persons, but the publicity which was given to this case should prove an obstacle to any process of presentation by guileless holders. The moral is that such notes should be signed in the Colony. If this is done by hand the labour is considerable, and we have known it to be stated that some signatures have been so unsatisfactory that they look more like forgeries than genuine notes. Other Crown Colonies have therefore adopted the practice of having the signature printed here. But a suitable stamping machine can be bought for about £24.

---

The prospectus of the new Elder Dempster and Co., Limited, throws a great deal of light on the late Sir A. Jones' varied enterprises. Many doubts were expressed during his lifetime as to their financial success, and certainly very few lights had any approximate

notion of their position. This was no doubt due to the grip which Sir A. Jones retained to the last on the management of his undertakings. There is no question now of their stability, and it is certain that the purchasers have made an excellent bargain. The West African trade is and always has been highly profitable. The Jamaica contract on the whole is believed to have worked out at a loss, but this was not taken up by Sir A. Jones solely from business considerations. The Bank of West Africa will now be clearly separated from the shipping business and this is a distinct gain, as there were considerable objections to the combination of these interests. It was an excellent move to secure the services of Lord Milner as chairman, and the bank is bound to benefit from the energy and ability which will be brought into the management by this step.

---

The author of the new handbook of Nyasaland remarks of the Marimba natives that their employment consists in doing just sufficient work consistent with obtaining the necessities of life, and avoiding all worry and vexation, which invariably follow if they seek to amass anything beyond the wants of daily life. They live a natural life, and accept death without complaint. Their troubles commence as soon as European ideas enter their environment. This type is a common one among savages. In their original state the one thing which stirred up a feeling of enterprise and pride was predatory warfare, and enforced peacefulness has had, it must be admitted, an enervating influence on tribes whose one virtue was courage. Moreover, the security created by the presence of civilised administration tends to break up the old organisation in every way. The chiefs lose their authority, and the communities are more or less dissolved. This process has gone on in the civilised countries of the world, but it has proceeded gradually and naturally, and other forces have grown up simultaneously. It is, of course, to the good that raids and disturbances have been put down, but this is followed by some weakening of character and responsibility. Wherever the British flag has established personal security for all, there is created an opportunity for individual outbursts of temper—unrest, to use the favourite term—which would not have been possible under the primitive regime. It is the price paid for peace.

---

The reputation of Antigua for sound administration will be enhanced by a record revenue for the year 1908-9. This result was in spite of the fact that the crop of sugar was short and cotton showed a falling off. In the other Leeward Islands however cotton has prospered; in the Virgin Islands the output has grown from £30 in 1904 to £2,531 in 1909. Prospects are good and capital invested in these islands may expect a fair return. The Colony has been free from serious disease and from any of the disasters to which the tropics

are, from time to time, subject. In his address to the General Legislative Council the Governor, Sir Bickham Sweet-Escott, pointed out an advantage to dwellers in the Colony which may well be envied. "Compared with rates of taxation in other Colonies, the rate of taxation in the Leeward Islands per head of population is moderate, ranging from 19/2 and 19/1 in the case of Antigua and Dominica respectively to 16/9 in the case of St. Christopher and Nevis, 11/11 in the case of Montserrat, and 5/6 in the case of the Virgin Islands. The Virgin Islands has the honourable distinction of being the most lightly taxed part of His Majesty's dominions, whilst the Falkland Islands, with their rate of £3 1. 5. per head, is second highest on the list of British Colonies, the highest of all being New Zealand, with a rate of £4 1. 8. per head of population. In the neighbouring Colonies of St. Lucia and Grenada the rates are £1 2. 10. and £1 0. 2. per head respectively."

---

The critical position in the cotton market lends special interest to the report for 1909, of the British Cotton Growing Association. Lancashire gave very inadequate aid to the first efforts of the Association, but the spinners and operators have recently responded well to an appeal made to them, and nearly £500,000 has been raised. There is thus a clear prospect that the work can be developed on sound commercial lines.

The experiments with cotton seed as fuel for motive power mentioned in the last report have been successful as far as they have gone, and the results of the plant, which has now been working in Lagos for several months, are quite satisfactory. Another plant is now being erected in East Africa, and it is intended to put up additional gas engines worked from cotton seed in Northern Nigeria and Nyassaland. Experiments are also being carried out with a seed cotton opener. The Association have now four hydraulic pressing establishments in Nigeria. The bales produced have given every satisfaction, and have a density of 28 pounds per cubic foot, or about 80 to 90 cubic feet for the ton weight. An additional instalment is now being erected at Kisumu, on Lake Victoria, and a further plant has been ordered for Nyassaland. It is proposed to erect presses in each colony as soon as there is a sufficient quantity of cotton to justify the expenditure; these presses will be available to all planters and will result in considerable saving in freight charges.

## CROWN COLONIES AND INDIAN IMMIGRATION.

The Committee which Lord Crewe appointed last year to consider the question of emigration from India to the Crown Colonies and Protectorates, and over which Lord Sanderson presided, has issued its Report. The Committee have held 71 sittings and examined 83 witnesses, and have made a close study of the large quantity of literature, official and unofficial, dealing with the subject. As was to be expected in view of the strong composition of the committee and the great amount of labour which they have devoted to their task, their Report is a document of great interest and permanent value. The system of emigration on a large scale from India to far distant countries has now been in operation for many years. Experience has taught many lessons to the governments concerned, and there have been repeated enquiries into the working of the system in particular Colonies, and in the districts of India in which recruiting is most constant; but there has been no enquiry quite so comprehensive in its scope as that conducted by Lord Sanderson's committee. A system which is necessarily highly artificial, and which is connected with so many problems the factors in which vary with changing circumstances, stands in need of a careful review from time to time, and it will be of great advantage to the Governments concerned to have experience obtained from many different sources collated and brought into relation.

In a historical retrospect which opens the report, the committee practically date the commencement of Indian emigration with the introduction of coolies into Mauritius after the abolition of slavery in 1834. Three years later the system of indentured emigration was denounced in Parliament, with the result that it was suspended, and a Committee was appointed in Calcutta to enquire into the whole matter. The majority of the Committee, whose report was submitted in 1840, were altogether opposed to further emigration, but one of the members, Sir J. P. Grant, considered that the evils which had been proved to exist were preventible, and in an exhaustive

## Crown Colonies and Indian Immigration. 15

study of the question he recommended the resumption of emigration to Mauritius and, more gradually, to certain other Colonies, subject to the necessary precautions. These included the appointment of a Protector of Emigrants, with extensive powers of control and supervision at the port of departure, the taking of security for return passages, and insistence on the Colonial laws applicable to Indian emigrants affording proper guarantees for freedom and prompt redress of grievances. In 1842 the Report came up for discussion in Parliament when a motion supporting the views of the majority was lost by 113 votes to 24. Emigration to Mauritius was resumed in the same year, and two years later it was authorised to Jamaica, British Guiana and Trinidad, the proposals put forward by Sir J. P. Grant being taken as the basis of the system. The numbers sent to the Colonies above-mentioned between 1842 and 1870 were as follows :—

Mauritius	...	...	...	351,401
British Guiana	...	...	...	79,691
Trinidad	...	...	...	42,519
Jamaica	...	...	...	15,169

During this period gradual improvements were effected in the method of recruitment in India, and few important questions connected with indentured emigration arose. But on more than one occasion enquiries revealed cases of neglect and mis-management in particular Colonies, and there were periods when emigration both to Mauritius and to the West Indies was suspended.

“Communications with distant colonies were in those days slow, and the Government of India had few sources of information open to it as to the condition of the emigrants while indentured in the colony or residing there after the expiry of their term. Further, while everything possible had been done by the Government of India to secure by legislative measures the welfare of the emigrants while on the voyage and under indenture, sufficient attention had not been paid to the responsibility of the Government for the proper treatment of the emigrants when they had completed their term of indenture and became merged in the general population of the various colonies. On the other hand, the planters and the Colonial Governments, in which the planting interest is generally powerful, did not at first appreciate the fact that Indians made excellent settlers, and that it was to the advantage of the colony to encourage them to settle down as free citizens and so contribute to the general prosperity. The aim of the planters, who had suffered so severely from the entire discontinuance of slave labour, was too often to acquire complete control over the labour market by means of regulations and administrative measures which aimed at compelling the coolie to re-engage himself on the expiry of his indenture, rather than encouraging free

settlers. The consequence of this feeling was that the laws relating to Indian immigrants introduced into several colonies gradually assumed a complexion less and less favourable to freedom, and, as the reports of subsequent Commissions show, they were framed and administered in a spirit of substantial injustice to Indian immigrants."

Commissions of enquiry were appointed in Mauritius, in British Guiana and in Natal, and their reports led to substantial amendment of the system in force. "With the measures taken by the various colonies to give effect to their recommendations, the history of serious abuses in connection with emigration to distant places ends, as far at least as British colonies are concerned." Indentured immigration has continued to all the colonies mentioned, with the addition since 1885 of Fiji, and in 1907 the numbers of persons of Indian nationality in the various colonies were as follows:—

Mauritius	...	...	...	...	...	264,000
British Guiana	...	...	...	...	...	127,000
Trinidad	...	...	...	...	...	103,000
Natal	...	...	...	...	...	115,000
Fiji	...	...	...	...	...	31,000

In approaching the question of the present attitude of the Government of India towards emigration, the report quotes at length from a very interesting correspondence between the late Lord Salisbury, as Secretary of State for India in 1875, and the Indian Government. The latter were invited to consider whether the time had not arrived when an active encouragement of emigration to British Colonies was desirable. "Having regard to the greatness of our Indian population," wrote Lord Salisbury, "and to the probability that, under the protection which the British Government affords from depopulation by war, and, as far as possible, from famine and other evils, that population must continue very greatly to increase, especially in the healthier and more densely peopled parts of the country where the numbers already press on the means of subsistence and the lower classes are at all times little removed from want, it appears to me that, from an Indian point of view, it is desirable to afford an outlet from these redundant regions into the tropical and sub-tropical dominions of Her Majesty, where people who hardly earn a decent subsistence in their own country may obtain more lucrative employment and better houses. While, then, from an Indian point of view, emigration properly regulated and accompanied by sufficient assurance of profitable employment and fair treatment seems a thing to be encouraged on grounds of humanity, with a view to promote the well being of the poorer classes, we may also consider from an Imperial point of view, the great advantage which must result from peopling the warmer British possessions which are rich in natural resources, and only want population, by an intelligent and

industrious race to whom the climate of these countries is well suited, and to whom the culture of the staples suited to the soil, and the modes of labour and settlement, are adapted. In this view, also, it seems proper to encourage emigration from India to Colonies well fitted for an Indian population." Accordingly a scheme was suggested under which the Indian Government were to give active encouragement to emigration, and by means of agents stationed in the Colonies concerned, to make themselves directly responsible for the accuracy of information supplied to would-be emigrants and the due performance of the terms of the contract of service. The Indian Government, however, in a lengthy reply expressed themselves as "clearly of opinion that any material departure from the permissive attitude which has hitherto been observed would be extremely impolitic." Objections had been taken to Lord Salisbury's proposals in some quarters on the ground that India, regarded as a whole, was under, rather than over, populated. But the Indian Government did not endorse these objections, pointing out that the effect of emigration could never be more than infinitesimal.

"The highest figure ever reached by emigration from Calcutta was 27,779 in 1858, and it has only in one other year been above 25,000: even if this number was multiplied by ten, which is far beyond the extent to which any countenance that Government could give can be expected to increase it, it would be but a trifling percentage upon the vast population of the North-Western Provinces, Oudh and Behar, which are the fields from which the emigrants are chiefly drawn."

Nor did they feel alarm at the effect of expanded emigration to the Colonies on the labour market of Burma and Assam. Their objections were based upon "the effect which the direct and active interposition of the Government in this matter would be likely to have on the minds of a people prone to regard with the utmost suspicion the acts and motives of their foreign rulers, and especially on the minds of the uneducated classes from which the emigrants are drawn; and to the difficulty and embarrassment in which the Government would become involved by undertaking responsibilities towards the Colonies on the one hand, and towards the emigrants on the other, which it would be practically impossible for it to discharge in a satisfactory manner."

Their objections were so serious that they felt it impossible to carry into effect the change in policy which Lord Salisbury had suggested, and the action of the Indian Government continued to be limited to the provision of facilities to the emigration agents employed by the Colonies.

The appointment of Lord Sanderson's committee led to a further expression of the views of the Indian Government, who proved to be even less disposed than their predecessors to give any active

encouragement to emigration from India. Their opinion was expressed in the following terms:—

“The purely neutral attitude adopted by Lord Lytton’s Government has been consistently maintained by the Government of India during the past thirty years, and nothing has occurred during that period to suggest that any modification of that attitude would now be justified. On the contrary, two serious factors in the situation have arisen, both of which must, in our opinion, tend rather to the restriction than to the encouragement of emigration. In the first place, although the proposal now before us only relates to emigration to the Crown Colonies of the Empire, we are unable to overlook the fact that any one of the more important Crown Colonies may eventually become a self-governing Colony. Of late years, the difficulties which have arisen from the emigration of Indians to Colonies that are now self-governing have increased enormously, and it is needless to draw your Lordship’s attention to the serious crisis with which we are now faced in, at any rate, one portion of the Empire, owing to the methods of self-governing Colonies in dealing with the status and rights of British Indians whom they had allowed, if not actively encouraged, to settle within their borders. It is impossible for us to disregard the fact that the history of the anti-Asiatic legislation in Natal and the Transvaal may at any time be repeated in others of the Crown Colonies, and we should therefore view with the greatest misgiving the adoption of any course of action which might tend to create racial problems of a similar nature in these Colonies. As an illustration of the fact that the apprehensions which we entertain in this respect are not without substantial foundation we may draw your Lordship’s attention to the situation which we understand at present exists in the British East Africa Protectorate. Indian settlers lived and traded in British East Africa long before the days of British rule, and their status in the country and their claims to political recognition are such that they cannot be overlooked. We believe, however, that these claims are not regarded with favour by the white colonists, that the Indians as a whole are disliked by them, and that certain areas are being reserved entirely for white colonisation; and it is within our knowledge that fears have already been expressed lest, when the country is eventually given self-government, the antagonism of the white colonists and the Indian traders and settlers may result in similar problems to those which have had such deplorable results in South Africa.

“The second factor to which we have alluded above is the shortage of labour in India, of which complaints are being made by nearly all sections of the industrial community.

“From the inquiries which we have instituted, we are led to believe that there is no irremediable shortage in the supply of labour in India, and that complaints on this subject are due rather to the

difficulty of tapping the available sources of supply than to any real shortage in the supply itself ; and we do not believe that any amount of emigration which could conceivably take place, even if Government were to abandon its policy of non-interference, would have a very appreciable effect on the labour market. It will, however, be readily understood that, so long as complaints continue actually to be made by Indian industrial concerns as to the difficulty of obtaining labour, any abandonment by Government of its existing policy in the direction of actively encouraging emigration would at once afford matter for adverse comment on the part of the commercial community, and would lay our Government open to the charge—however little foundation there might be for it—of subordinating the acknowledged needs of the community to the problematical requirements of the Colonies in response to pressure from the Imperial Government.

“ There is one further consideration which we are unable to overlook, namely, the impression which would be created in the minds of the people by any active encouragement of emigration on the part of Government. We regret that we see no grounds for believing that such a policy would be looked upon with less suspicion now than was anticipated in 1877. On the contrary, the readiness which, at any rate in one instance, certain sections of the native press have recently shown to accept and publish, without any attempt at verification, the highly coloured story of the harsh treatment to which Indian emigrants to British Colonies are subjected gives us no reason to hope that the motives of Government would be less exposed than formerly to misinterpretation and misconstruction. It is a significant fact that, although numbers of emigrants return annually from the Colonies, bringing with them in many instances large accumulated savings, no perceptible stimulus to emigration appears to result ; and it is difficult to explain the general reluctance to emigrate, of which the Emigration Agents complain, except on the assumption that there exists in the minds of the people an ingrained suspicion of the methods and motives of any person who makes the promotion of emigration his business.”

Lord Sanderson's committee accept the view expressed that emigration cannot be expected to exercise any perceptible effect on the prosperity of India, but they point out that it is admitted that such effect as it does exercise is beneficial, and that the advantages to the individual emigrant are “ unquestionably great.” But in recommending the continuance, on this and other grounds of indentured emigration, they lay down certain very important limitations. They regard it as “ an indispensable condition of indentured emigration that Indians who have completed their term of indentures should be in all respects free men, subject to no labour Ordinances and with personal privileges no whit inferior to those of any other class of His Majesty's subjects resident in the Colony.” They consider that

they should have the option of returning to India or settling as free citizens in the colony; the only exception which they would permit would be in the case of labourers engaged in India by the Government of a colony for railway construction or similar work. And they decline to recommend indentured emigration to any colony or protectorate where there is no agricultural land available for new settlers. They regard it as the natural ambition of Indian labourers to rise to the status of peasant proprietors, and consider that the gratifying of this desire is as beneficial to the colony as to the Indians themselves. "The evidence before us leaves no room for doubt but that the large majority of the immigrants who stay on in the colonies succeed in life. Many of them acquire land. Others engage in retail trading and in miscellaneous occupations. The contrast between their position in the colonies and that which would have been within their reach if they had remained at home is generally striking." At the same time they find that there is some ground for complaint as to the frequency with which recourse is had to the criminal law to enforce the terms of the labourers' contracts, and in the case of three colonies, British Guiana, Trinidad and Fiji, they have suggested a local inquiry into the matter. They also consider that it would be of advantage for the Colonies who receive emigrants from India to be visited from time to time by an Indian officer, in accordance with a suggestion made by the Indian Government, but never put into operation "because the whole system of indentured immigration has of late years worked so smoothly, and because, so far as India is concerned, its beneficial results have generally appeared so patent."

The Committee find a good deal to criticise in the methods of recruitment in India. To the enlistment of persons unsuited for agricultural labourers, "priests, barbers, jewellers and men of that kind," they ascribe the frequency of convictions for breaches of the labour laws, which is "the only serious blot on the system of indentured emigration."

"It is clear that a certain proportion of the emigrants are casual persons picked up in the vicinity of towns and markets by recruiters who are not altogether scrupulous as to their methods, and that they agree to emigrate without knowing much of the conditions which lie before them; that many even of the emigrants who are agricultural labourers of the congested districts leave their homes without any very clear conception of their prospects; that the recruiters do not penetrate into the villages where they are likely to meet with such persons and endeavour to induce them to emigrate with their families; that the field in which the recruiters work is extensive and far distant from Calcutta, the headquarters of the Emigration Agent, so that proper control by him is in the nature of the case impossible, while the supervision exercised by the

inspectors and the sub-agents is not effective. The result is that emigration to the colonies is generally unpopular and is regarded with much prejudice by the influential and respectable classes. Another result of casual recruitment is that the recruiter has no means of acquainting himself with the occupation, character, or antecedents of the recruit, and for this reason unsuitable persons are chosen, who afterwards prove the bad bargains of the colony and are returned to discredit the system. And a third result is the mysterious disappearance of persons who are recruited at a distance and do not communicate with their own homes before they leave the country."

They consider that these results could be avoided if recruitment were more concentrated and limited to certain districts, and a responsible agent were stationed at Benares, who would tour the recruiting area and supervise the operations of the recruits. "The advantages to the ordinary labourer of a term of indenture in the colonies have only to be better known to be fully appreciated," and it is with the object of preventing misconceptions and misunderstandings that these recommendations are made.

Dealing with the effect of Indian immigration on the Colonies concerned, the Committee find it to be "an undeniable fact that in tropical climates, where the needs of the indigenous population are few and simple, and where there is an abundance of fertile land open to the use of that population for the satisfaction of those needs, it is impossible to obtain from local sources, except by compulsion, a sufficient supply of labour for the development of industries dependent on steady and continuous work. Wherever these climatic and economical conditions prevail, recourse must be had for the prosecution of such industries to the introduction of some alien race whose previous traditions and methods of life have inculcated habits of steady and regular work." But the system ought not to be continued beyond the period when it is really necessary to secure a regular and trustworthy supply of labour, or where its effect is merely to reduce the remuneration of the free labour supply available. The committee have not learned of any instance where indentured immigration has been proved to have had the result of reducing the wages of the older colonists or native population, and they find that the immigrants "are the means of providing for those classes opportunities of congenial employment which these would not have otherwise enjoyed." In concluding this section of the report the Committee take occasion to deal with the imputation that indentured immigration partakes of the nature of slavery.

"Our unhesitating opinion, after examining the best and most authoritative evidence that we could obtain on the subject, is that, whatever abuses may have existed in the more remote past, no such charge can be substantiated against the system as it at present exists and has been in practice during the last 20 or 30 years.

“The restrictions placed on the immigrants are not in their practical operation excessive. The regulations in some colonies as to passes, etc., seem to us in their wording to go somewhat beyond the necessities of the case, but they are not in fact strictly enforced, and it must be remembered that they have been designed, in part at least, for the protection of the labourer as well as for the convenience of the employer. They do not alter the fact that outside the terms of a contract, the principal conditions of which have been twice explained to him before he enters into it, he is for all real purposes a free man, whose rights are carefully watched over and guarded by a special staff of Government officials. It is no doubt on the efficiency and rectitude of those officials, and upon the pursuance of an enlightened policy by the employers, that the welfare and comfort of the labourer must depend. But this is equally true of many other kinds of employment in all parts of the British Empire, not excepting the United Kingdom. The system must, like others, be judged by its results, and there is a general concurrence of opinion that, so far from exercising any depressing or debasing influence on the immigrant it does in fact encourage in him the growth of independence of character.”

The Committee summarize their conclusions on the general question as follows :—

That subject to certain recommendations which we shall have to make in regard to individual colonies, the system of indentured immigration as actually worked is not open to serious objection in the interests of the immigrant labourer.

That Indian immigration is of the greatest assistance in developing the resources of some of our tropical colonies, and in increasing their prosperity.

That in the present condition of India, indentured emigration is the only practicable form of emigration to distant colonies on any considerable scale.

That emigration under indenture for private employers should be permitted only to such colonies as offer an opportunity to the time-expired immigrant to settle in an independent capacity on the land.

It follows that emigration of this nature should only be permitted to such colonies as have spare land capable of development.

That it being obviously to the advantage of a colony to develop its spare land, there is no objection to the Government of such colony assisting the employers of labour in bringing in immigrants who are at first at the disposal of the employers but subsequently contribute independently to the development of the resources of the Colony.

The report proceeds to consider in detail the circumstance of each Colony or Protectorate to which Indian immigrants are at present

sent, or to which it has been suggested that they might be sent. In the space at our disposal it is impossible to do more than refer to a few of the salient features of this part of the report.

The extensive Indian immigration to Ceylon proceeds without any system of indenture, the proximity of the Colony to India rendering it easy for recruitment to be carried out through private agencies. The Committee refer with approval to the recommendations of the Ceylon Labour Commission, and they find the system of immigration in existence to be "both natural and beneficial."

In the case of the Straits Settlements and the Federated Malay States indentured and unindentured immigration exist side by side; but of late years the latter has increased far more rapidly than the former, and the ordinary period of indenture is for no more than 600 days. In the case of the Federated Malay States there has been a disquietingly high death rate on certain estates, and the Committee recommend the early discontinuance of indentured immigration. The announcement that indentured immigration to the Federated Malay States is to be brought to an end has already been made in Parliament.

The Committee find that Mauritius has been mainly dependent on Indian immigration for its economic development, and they enforce this conclusion by an interesting comparison with the French island of Réunion. But the population, of which the Indians form 72 per cent., has now attained a density of nearly 559 to the square mile. The demand for fresh immigrants is small and intermittent, and there has been an admitted growth of poverty in recent years, coupled with "a marked increase of pauperism in the Indian population" during 1908. In these circumstances the Committee find themselves unable to recommend a continuation of the system of importing labour.

In treating of British Guiana, the report quotes the opinion of Dr. Comins, who visited the West Indies in 1891 on behalf of the Government of India, that this Colony "in consequence of the long-continued efforts of legislators and planters has brought its system for the beneficial control of indentured labour to a higher pitch of perfection than any other Colony." The law, somewhat drastic in the wording of its restrictions, is administered with little resulting hardship, and among such persons in the recruiting districts of India as are able to discriminate, British Guiana is a popular Colony. But the number of prosecutions for offences against the Immigration Ordinance is excessive, and a local inquiry into the subject is recommended. The arguments against Indian immigration put forward by the People's Association of British Guiana are discussed at length and finally dismissed as unsound. On the other hand a large increase in the number of emigrants, advocated by some of the planters, is not recommended in view of the possibility of a set-

back to the sugar industry and the absence, in the present undeveloped state of the Colony's natural resources, of other suitable fields of industry.

The Immigration Ordinance of Trinidad is closely similar to that of British Guiana, and the sections of the report dealing with the two Colonies have much in common. The high degree of prosperity attained by a large section of the Indian population is emphasized, and the committee are clearly in favour of the continuance of indentured immigration. On the other hand the frequency of prosecutions for "labour offences" calls for enquiry, and it is suggested that the time has come when the Indian community might be represented in the Legislative Council.

In the case of Jamaica Indian immigration has been on a comparatively small scale, and its justification lies not in the absence of a local labour supply but in the disinclination of the Creole labourer to supply the regular and systematic work required by the economic conditions of a large estate. The Committee endorse the view of Sir Sydney Olivier that immigration does not operate to the disadvantage of the Creole labourer, and they recommend its continuance. They find that "the general condition of the Indian immigrants in Jamaica is satisfactory, both during their term of industrial service" and after its expiry. It is suggested that a definite scheme of land settlement to promote the acquisition of land by term-expired immigrants would be advantageous.

The Committee find themselves unable to recommend the resumption of Indian immigration to any of the Windward Islands, where the conditions as regards the existing labour supply do not appear to them to justify the proposal.

In the case of British Honduras the Committee consider that the introduction of indentured Indian labour is distinctly desirable, provided that the conditions laid down in the first part of their report are satisfied. They lay stress on the large undeveloped area of land, the promising agricultural potentialities of the Colony, and its very sparse population. They consider that it may be confidently anticipated that the condition of Indian immigrants would be satisfactory, and they foresee no likelihood of friction between them and the Creole population.

The view taken as to Indian immigration into Fiji is generally favourable. Attention is drawn to the excessive number of prosecutions for offences under the Immigration Ordinance, and it is stated that "a section of the white population, imbued with the prejudice of the young nations of the Empire against the coloured man, while recognising the utility of the Indian for the purpose of sugar cultivation, does not welcome his competition in trade, and is inclined to resent his settling down as a free citizen." But a large influx of white settlers is improbable, the general condition of the

Indian population is one of prosperity, and their contribution to the general progress of the Colony is undoubted.

In the Seychelles there is some demand for Indian labour, the satisfaction of which must depend on the practicability of providing transport from India. In West Africa the Committee can see no field for the employment of Indian agricultural labour.

In East Africa the Committee find that there are considerable tracts of land along the coast which could be more rapidly developed if imported labour were obtainable; but they are unable to recommend Indian immigration under indenture, except for public works service directly under Government, "unless the immigrants are offered the option of remaining in the country after the expiration of their contract on an equal footing with the rest of the population, and with opportunities for settling on the land in any part of the Protectorate which may be suited to them." In view of the strong objections taken by the white population of the upland districts to any measures tending to increase the resident Indian population, this condition is not likely to be satisfied.

"In the Uganda Protectorate, where a population greatly diminished in former times by war and slave raids has been still further reduced by famine and disease in recent years, there are large tracts of country where apparently Indian colonies might with advantage be planted. It would, of course, be necessary that experiments of this kind should be tried at first on a small scale, and with every precaution to avoid interference with the native races. But a primary, and to all appearances insuperable, difficulty presents itself in the absence of funds for the initial expenses of the venture." There is no opening for the employment of indentured labourers.

## THE NATIONALISATION OF RAILWAYS.

In this country the railway system has been entirely the outcome of private enterprise, partly because the industries concerned have been well organised from the first, and partly because capital has been readily supplied. In many other countries the Government has had to step in because these conditions were absent. In some, both systems exist side by side, popular preference in favour of one or the other varying greatly from time to time. There is, however, always present on the continent of Europe a consideration which is not felt in Great Britain. This is the international competition for traffic. Thus the rivalry of France, Belgium, Holland, and Germany, on the northern side has had a powerful influence on the character of the railways. In such a case there is a national reason for low competitive rates, and this leads to the policy of nationalising the railways which lie at the great gates of commerce and of instituting special tariffs in the interests of the industries of the country. This movement does not by any means imply that it has been found by experience that railways are better constructed or managed by the State than by private means. There is a considerable body of opinion that this is not the case. The determining consideration has been simply that a sacrifice of railway revenue would be more than made up by the benefits that resulted to trade, and that the international competition made such a policy practically necessary.

In this connection the history of the railways in Belgium is particularly instructive. This country, like France, began construction about 1833, and the first lines were constructed and opened by the State. After a few years the financial results were found so unsatisfactory that concessions were granted to companies, but from the year 1871 the policy has been constantly followed of State ownership, and many private lines have been bought up. At present the State railways cover some 4,100 kilometres, and the private railways only 530. It is easy to see that the reasons for this process grow stronger as it proceeds. While there are two systems there are inevitably complications and disputes, and as, on the whole, the State railways are more generously financed the trend of popular opinion and pressure is in their favour. The financial details are contained in a recent Board of Trade report (Cd. 5,106). The re-purchase of the railways by the State was followed by a general reduction of

rates, both on the State lines and, as a matter of course, on those belonging to private companies. Thanks, however, to the development of the commerce and industry of the country the total receipts are sufficient to cover the interest and redemption of the capital.

For instance in the year 1907, the "capital utile," which represents the actual cost of the railway system open to traffic and its equipment, amounted to 2,395,664,033·44 francs, and the net profit was 81,214,030·70 francs; deducting the share of receipts payable to the companies and the rent of the line from Spa to the frontier, which amounted to 5,742,625·65 francs, the actual net profit amounted to 75,471,405·05 francs, which gives a dividend of 3·29 per cent., a strikingly small rate of interest for a line whose receipts per kilometre amount to about 64,849·98 francs.

It should be added, as the case of English railways is very different, that the State railways are not subject to taxation, and no taxes are levied on either passenger or goods traffic.

Special import and export tariffs form a large proportion of the whole body of rates. There are numerous special tariffs for international traffic, and combined sea and rail rates with certain shipping lines. Thus there is a combined rate with the "Red Star Line" to Antwerp, but such rates are not extensively used, as they are in Germany, as the low export rates by rail leave often little, if any, advantage to them.

The extent of State ownership in Belgium prevents any serious competition between the full gauge railways, and goods go by the shortest route. The State supervises the rates on light railways privately owned, and prevents any competition with State lines. Thus the rates are uniform and there is an absence of waste.

There has been since 1881 a remarkable development of light or secondary railways known as the "*chemins de fer vicinaux*." About 3,216 miles are now being worked, and considerable extension is in prospect. This work is done by a company called the National Society, but the State contributes a large proportion of the capital, and the provinces and the communes can also take up shares. This arrangement no doubt stimulates construction; the capital subscribed privately is very small, and this is not surprising, as the average dividend is only 3 per cent. The canals are State owned, and the railways are not allowed to crush them; they do not pay directly, but it is considered that there is an economical advantage in such a country in retaining this cheap form of transport, and enlargements at the public expense are contemplated.

It will thus be seen that the policy of the Belgian Government is eminently paternal. Its chief aim is to secure the welfare and commercial prosperity of the country. Neither courage nor enterprise has been lacking to carry out any scheme which promises to benefit the community. It is this spirit which inspires the relations of the

Government not only with the main railways but also with the waterways and the light railways, and in pursuance of this policy the State has acquired a large proportion of the main railways since 1870.

It is a moot question whether these light railways yield a profit or not, but if there be such a profit it is certainly a comparatively insignificant one. With regard to the waterways, it is evident that they are run at a considerable annual loss, whilst the State takes up 50 per cent. of the shares of light lines and guarantees the interest to private shareholders. These light railways are admirably adapted for fostering the interests of agriculture and small industries.

The commercial section of the community at the large centres and ports appears to be very favourably served by the Government railways both as regards the transport of goods and the prompt settlement of reasonable claims, this being no doubt partly due to the desire of the State to foster the import and export trade and assist local industries. The general opinion amongst the traders concerned seems to be that the railways are administered on commercial principles, which point of view can be well understood, seeing that the railway rates are reduced to an extent which permits of very little profit or none at all, and that the transport regulations such as the packing of goods and demurrage are not enforced with any degree of rigidity.

If it is a fact that a loss is sustained on the working of the main railways for the benefit of the general community, the State does not permit private or public bodies to profit at the expense of the taxpayers. For example, the State keeps control of the rates on the light railways, and by raising them when necessary prevents any threatened competition with the main lines. Further, there is no competition in rates between the State and privately-owned railways, as a proposed rate which interests any of the systems is submitted for their approval before being put into force. Again, little or no competition for the carriage of goods can exist owing to the principle of the "shortest route." As regards the passenger traffic every encouragement is given to the population and to visitors to travel extensively.

Season tickets are issued which are available over all the railways. The price of a third class yearly season available over all lines is about £15, but if paid for by quarterly instalments it amounts to about £16 10s. In addition to these, 15 and 5 day tickets are issued available everywhere in Belgium, the cost of the former being under £3 10s. for the first class and £1 for the third class, no limit being placed on the extent of the travelling so long as this is within Belgium.

In France concessions were at first granted to private companies, but in 1842 the State undertook to carry out an extensive policy of railway construction. The State was to construct the earthworks and build the bridges, stations, viaducts, &c., while the companies to whom the concessions to operate the lines were granted had to lay

the rails and to provide their own rolling stock, the agreement being that the railways should ultimately revert to the State, the rails and rolling stock being purchased at a valuation.

In the interim between the years 1842 and 1852 a considerable number of small independent lines were constructed, but in 1852 and in the following years the majority of these became incorporated into six big systems, forming in 1857 what are now the Northern, Eastern, Paris-Orleans, Paris-Lyons and Mediterranean, Southern and the recently State-purchased Western. After 1857 public confidence was shaken owing to the large expenditure on branch lines, and the necessary capital for fresh lines was not forthcoming. The State thereupon stepped into the breach and by six laws of 1857 and 1859 ratified the Conventions which had been passed with the six great Companies.

The principles followed with regard to the guarantee of interest were the following :—

The lines of each company were divided into two classes, first the new lines, and secondly the old lines. The State guaranteed interest at the rate of 4·65 per cent. on all capital expended on the construction of new lines, whereas the old lines did not enjoy this advantage. The net receipts of the old lines were to be employed in the following manner :—In the first place to secure the payment of interest and writing off of the debentures issued for their construction ; secondly, to complete the interest on debentures issued for the construction of the new lines, as the State guarantee would not be sufficient to enable the necessary interest to be paid ; thirdly, to pay a dividend to the shareholders which would not be inferior to those of preceding years ; and any surplus then remaining would be employed in decreasing the deficit on the new lines. When the net profits of both the old and the new lines exceeded the total amount of the guarantee of interest and of what may be termed the reserved revenue of the old lines, such surplus would be handed over to the State for the repayment of any sums paid by way of guarantee of interest, which sums were only considered as loans bearing interest at the rate of 4 per cent. per annum.

The Western Railway was bought up in 1909, and the results are still to be seen.

Concessions which are now granted are all temporary and are for a period of 99 years, at the end of which the State enters into possession ; it has also the option of purchase at any time on its average revenue for the last five years out of the past seven.

The State control of all railways is very extensive, as a necessary condition of the intimate financial relation between the State and the companies. Special export rates are granted.

In Italy the working of the railways was in 1885 ceded to private enterprise subject to 20 years' notice, and in 1905 it was resumed

after this notice by the State. The common form of concession now is for construction and working with power to the State to take over working after construction. The arrangement by which the railway companies were subject to 20 years' notice was undoubtedly a bad one. No company could work with vigour and enterprise on so uncertain a tenure.

Expenditure on railways requires long years to fructify, and although there has been private management lasting for a period of 20 years, it must not be forgotten that there was always a State control on railways, *i.e.*, a control over expenditure in the shape of provision of rolling stock, &c. It may be that the many complaints relating to the working of the private railways were probably responsible for the termination of their leases, but the conditions under which the private lines were operated, and against which they had no voice, must have been in a great measure responsible for the shortcomings for which they were held to blame. The purchase of the lines is said to have been conceived and carried into effect at very short notice, and the resultant chaos was very serious: insufficiency of stock, accommodation, &c., produced complete disorganisation. To make good these deficiencies, heavy expenditure has been necessary.

There is a special export tariff, numerous inducements in the shape of various forms of tickets are given to encourage passenger traffic, but owing to the insufficiency of accommodation delays are frequent.

It is too early yet to express any opinion on the result of nationalisation in Italy. Some step was clearly necessary in view of the condition with which things had degenerated, but it must be recognised that the private companies had not had a fair chance. The chief objection urged against State management came from traders who had obtained special concessions to encourage some industry, but the Italian Government appears to recognise the importance of some elasticity in this matter, and on the other hand considerable abuse may be made of such a power by private owners. The freight charges, especially the through rates, are on the whole low.

The above cases give typical examples of the struggle between State and private ownership. It is clear that there is a strong tendency in favour of the former. The foremost reason for this is, as has been remarked above, that cheap and quick transport is a public necessity, but there are other grounds. The State can always raise capital on better terms than the individual, and capital expenditure, it must be borne in mind, is continually going on over existing lines in extensions and improvements. Then not only are Government rates low, but they cannot be manipulated, as has been done in the United States, to take an excessive share out of an industry when it has been established. There seems

to be no evidence of waste or mismanagement on the continental State railways as compared with private railways. Certainly in America great feats of economy have been performed on occasions, but it may fairly be argued that they were rendered possible by rivalries or preference which could not have grown up under a State system. There are some apprehensions that a Government will be less able to deal fairly with the workman than a company would. There is at any rate on the Continent no indication of this. In both cases public opinion on the merits of the dispute exercise a great influence, and if a Government believes that this power is on its side it can be at least as firm as a company and much more drastic in its methods. Thus on the 12th October, 1907, there was a general strike at Milan as a protest against the ill-treatment of workmen in a conflict with the public forces. The vast majority of the staff of the railway joined the strikers, and their example was followed by other centres, such as Turin, &c. The strike lasted for two days in Milan, and one or two days in other localities, the total number of railway employees on strike being 6,700. As a result 16 employees were dismissed the service, 114 were reduced in rank, 640 had their increase of pay deferred for two years, and 5,706 for one year, whilst 242 were suspended for a period varying from 6 to 12 days with loss of pay. The 16 dismissed employees and six of the others appealed to the Council of State, but only in one case was the appeal granted.

There is, however, one characteristic of State ownership which is often detrimental, and this is the practice of making promotions in order of seniority over the whole system. This entails numerous removals, and traders have many occasions to regret the loss of officials who have acquired an intimate knowledge of the local circumstances. Many complaints have arisen on the Continent on this score, and no doubt it is politic to temper the principle of seniority in favour of local experience.

The British Dominions and the Colonies have not had the difficulties with which the Continent has had to struggle. They started, with few exceptions, with the principle of State ownership, and the results on the whole have been amply satisfactory. The system leaves room for private work in construction. The best opportunities for this are when the work to be done can be specified with something like precision, so that tenders can be invited and considered on a definite footing. This is made easier by letting the work out in sections if local contractors are available and suitable. A contractor has also often an advantage in the supply of labour, as experience has taught him where to go for it and how to manage it; in this matter he is a more or less permanent employer, which the State is not. The disadvantage of the contractor as compared with the State in finance may be met by the State supplying the materials, and leaving to the contractor only the actual construction.

## AGRICULTURAL BANKS.

Every country with a large agricultural population is interested in the question of agricultural banks. For one reason and another the rate of interest paid by the cultivators of land is on the whole extraordinarily high. The primitive conditions prevailing in a rustic land are the main cause. The worker does not understand the price he pays for a loan, and so long as he can borrow he does not reckon the cost. Accordingly the interest may be as much as 100 per cent., and in fact is only limited by the peasant's absolute necessities. The misfortune is that the habit of borrowing is increasing. Civilization of the modern type spreads, and forthwith things which the native never thought of possessing become necessities. He might pay for them by doing more work, but why do this so long as the money-lender is complaisant? If the loan was spent on the land there would be some good result, but this is the exceptional case. The end in some places is that every village capitalist becomes a professional money-lender, and eventually the rest of the population is at his mercy. No improvements in cultivation or rise in prices can avail against the system. In Ceylon "the great increase in the price of cocoanuts of late years should have benefited the vast mass of the poor villagers largely, and have enabled them to get more or less out of the clutches of the Chetties and the village money-lenders; but that it has not done so is explained by the fact that while the Chetties lend on mortgage of the lands, charging interest in money the village lenders lend or advance on agreement to be repaid in produce in a number of years, the cocoanuts being priced at such a low rate that the money equivalent of the interest works out at 60 per cent. to 75 per cent., and even more. To give a typical example: a sum of Rs. 500 may be advanced to a villager who has an average crop of 2,000 nuts a picking, or 12,000 a year. Repayment of the advance will be taken by delivery of the nuts at Rs. 18 or Rs. 25 a thousand. It will thus take him  $2\frac{1}{2}$  years or  $1\frac{3}{4}$  years to work off the advance, while the nuts are worth at least Rs. 480 a year; besides, there is the fact that the principal is being substantially reduced every two months. With such a

ruinous system prevailing, it is little wonder that the villagers are always in a chronic state of want." (Ceylon, VIII., 1910.)

So far as borrowing proceeds from personal extravagance and not from developing the land the mischief is beyond the remedy of a State-aided bank, and this fact is sometimes urged against any proposal of the kind. It may be easy to show that villagers do not in fact devote the money now borrowed to the lands. The only way of dealing with professional lending of this description is to provide for the registration and control of usurers. But there remains the question of borrowing for good reasons, and of the educational value of a sound system. Where agricultural methods are of the primitive order borrowing is justifiable, and in fact should be encouraged in order that modern appliances may be bought and new products cultivated, but no good can be effected unless the rate of interest can be brought down to a reasonable commercial figure, based on safe investment. The difficulty is to make a start in this direction. Natives as a rule do not understand what combination is, or what it does. The Government therefore has to step in and point the way. It is clear that the help given should be carefully limited. If it is once believed that the bank is a sort of Government department the members would never try to control its proceedings and the movement would not spread. The institution must be of the nature of a local co-operative society, and the first active steps must be taken by the people of the locality. But a small Government advance vastly facilitates matters at the start. Sir Frederick Nicholson, in his Report on Land and Agricultural Banks in the Madras Presidency, writes: "It is found by experience that small State advances for initial expenses go very far in promoting the establishment of village banks; many inchoate banks have been stopped in the initial stage by the cost of preliminary expenses, which necessarily fall on the promoters; such assistance should be moderate and temporary, not exceeding one or two thousand rupees for each bank, and repayable by annuities within, say, ten years."

In India such co-operative societies are given the following special privileges:—

(1) Exemption from income tax, stamp duty on documents, and registration fees.

(2) Exemption from attachment in court of the amount subscribed to a society by a member.

(3) A first claim on crops raised from seed purchased with money lent by the society and on cattle and implements similarly purchased.

(4) Permission to open a public account in the nearest Post Office Savings Bank.

(5) The services of a Government officer to help and advise the societies and to audit their accounts yearly, so that the public may have full confidence in them.

The last privilege is a most important one—all societies established should be audited by a Government officer. In the United Provinces Government has sanctioned a sum of Rs. 50,000 in each province as a loan to rural societies, *the amount lent in each case not to exceed the amount actually deposited by the members*. This provision is of importance, and should be the invariable rule wherever Government assistance is granted.

In Eastern Bengal and Assam the Government has offered to lend to co-operative credit societies a sum equal to what the members raise by their deposits, free from interest for three years, and thereafter bearing interest at 4 per cent. per annum.

The object to be aimed at is not merely to provide a means of borrowing but also to teach the people the habit of saving and the reward of economy. Most peasants have at some times if not always some money hidden away, but it is not enough for any serious improvement and so lies idle. But if several men can be induced by the offer of interest and the Government protection to put in their money as deposits, there will be money available for some of them, and as a body they can borrow money on much better terms than any one could individually, both because the security is better and because the process is more convenient to the lender. The local character of each society should be jealously guarded, for in this way only can the people be educated to thrift and providence, but in a large country there is no reason why a central board should not be established which would lend money to the small and scattered societies. In many cases the planters will lend money and help generally; the enemy is not the landlord or the employer but the usurer.

The following is the procedure in India. If the cultivators in any village wish to start a village bank, the first thing for them to do is to meet and discuss the matter among themselves. If the persons who meet think that it is a good thing, they should proceed to make out a list of the names of those who wish to join. They must remember that all the members will be jointly and severally responsible for all the debts due by the bank, and should, therefore, refuse to enter on the list the name of any man of whose honesty they have any doubt, or who is known to be careless in money matters, and dilatory about paying his debts when they fall due. Only the names of such men should be entered who are known to be strictly honest and who will pay their debts if they can. When this list has been prepared, the persons whose names are included in it should proceed to choose three of the members to serve as a panchayat. The panchayat will have to manage the business of the bank on behalf of all the members, and so they should be the most intelligent and most respectable of the members. When the panchayat has been chosen it should choose one of its members to be sarpanch.

The next step is to ascertain how much money the members themselves are prepared to deposit. The Government has promised to advance free of interest for three years as much money as the members themselves deposit, so every effort should be made by the members to deposit as much as they can themselves.

Having ascertained how much the members are prepared to deposit, it is necessary next to find out about how much money they will need in loans for the first year. Suppose there are 20 members, and together their deposits amount to Rs. 100, Government will lend Rs. 100 more free of interest. Total Rs. 200. Perhaps these 20 members will require Rs. 400 for the first year's working. They have consequently to raise Rs. 200 more in order to have sufficient for the first year's working. They should go to the local money-lender and ask him whether he will lend them that amount on their joint security at a moderate rate of interest, say, Rs. 6 or 7 per cent. per annum, and also whether he will agree to accept repayment of the principal by instalments of Rs. 20 annually from the beginning of the 6th year after the loan is given, interest being, of course, payable yearly as it falls due. Perhaps the local money-lender will agree. If he does agree, the next step is to apply to the District Officer of the district that the society may be registered as a Co-operative Village Bank. This will cost nothing, and the District Officer will provide the society, free of charge, with copies of the rules and the by-laws. If the money-lender refuses to lend the money, the society should apply to the organization society at the headquarters of the district, or to the District Officer, or to the Registrar of Co-operative Credit Societies, Lucknow, giving particulars of what has been done, and what money is required, and probably the money can be found. The members should at the same time give information as to the amount they are prepared to deposit, whether in grain at each harvest, or calculated at Re. 1 or Rs. 2 per plough annually.

The District Officer or Registrar will not only give the bank help in raising money, if that be necessary, but will also give instructions as to how the accounts should be kept, how the business should be managed, and on any other points in which help may be required. Model by-laws and a model set of accounts with notes as to how they should be kept have been prepared. If in any village ten or more persons wish to join to form a bank they can obtain copies of these free of charge by making application to the District Officer or Registrar.

The system was only introduced in India in 1904 and the result has been extremely satisfactory. Within four years 1,357 societies were established, with a membership of 150,000 members. No doubt the system will be introduced in many other places where the circumstances are similar.

## COTTON-GROWING IN JUBALAND.

Jubaland is bounded on the north-east by the River Juba, which divides it from Italian Somaliland. It possesses a good harbour in Kisenayu, which will form the key to the trade of a large territory. The Juba has been called the Nile of East Africa, and indeed in many respects it closely resembles the great river which has given Egypt her wealth. It is navigable for steamers of light-draught for about 450 miles for six months of the year. It is subject to periodical inundations which cover the land for some miles on either bank and leave a fertilizing deposit in which the natives plant maize, millet and various other crops. The remarkable resemblance between the soils and climatic conditions of the valley of the Juba and those of the Nile has attracted the attention of many Italians. Signor Carpenetti has taken up about sixteen thousand acres of cotton-growing land, has imported a large amount of machinery, including steam pumps, ploughs, &c., and is vigorously engaged in establishing a big industry. Signor Tittoni, a nephew of the Italian Colonial Minister, in conjunction with the Marquis Afan de Rivira and Dr. Fanelli, has also acquired some large tracts of land, and is actively engaged in cotton planting. In all, upwards of 300,000 acres of land on the Italian side have been applied for and about 70,000 acres on the English side. The cotton is equal to the best Egyptian, long in staple, and of excellent quality. One or two cotton planters, who have had a successful experience in Lower Egypt, have taken up land and planted. One writes: "We have on the land lying along the Juba river a Nile silt with a young Nile feeding it, and our cotton showing eight inches out of the ground is equal to the best Egyptian plants of the same age."

The mouth of the Juba river is at Gobwen, and the bar can be crossed at high tide by ships drawing 8 feet of water, indeed careful soundings show about 14 feet in the shallowest part of the channel. The river is wide and deep enough for boats drawing 2 feet 6 inches. It was originally explored by Vanderdecken in 1865, who took up a side wheel steamer 480 miles to the commencement of the rapids. In

addition to the inundations which fertilize the ground there is a moderate rainfall during the months of April, May, June and July. The winter months are practically rainless. A six years' record of rainfall has been kept at the coast, and averages about 12 inches per annum. Thirty miles inland there is double the rainfall and further north still more.

The banks of the Juba are thickly populated by a mixed race of escaped slaves from the Somalis. These people are docile and inoffensive, and are agriculturists, whilst the Somalis are pastoralists with large herds of cattle and goats which they move from place to place. Numerous villages are dotted up and down both banks of the river, some of them quite important little places. Indeed, over the whole six hundred miles a large population must be settled. Bardera is the main trade centre through which pass the caravans for the South, laden with ivory, hides, coffee, wax and cereals, and a scheme is now in hand to establish a trading station opposite Bardera at Serenli. By this means most of the goods would be caught before they enter Italian territory, transhipped into lighters, taken down the river and loaded into ocean steamers at Kismayu. At present the caravan route takes six to eight weeks and costs £8 a ton. The steamer route would not take as many days and the saving to the Arab merchants would be great, even if the steamer charged as much as the caravan. The Italian Ports of Barawa, Merka and Mogadisho are open roadsteads, useless in bad weather, and the expenses and delays consequent upon such a route no doubt have a tendency to limit the trade. It is reasonable to assume that given quick transport and low rates double the business could be passed through Kismayu that now passes through the Italian ports, and yet these support two large steamers during the greater portion of the year.

The Boran country lies on the southern slope of the Abyssinian mountains and extends far into the plains. The country is extremely rich and the land fertile. The people are peaceable and industrious, and produce large quantities of grain of different kinds, cotton, ivory, rubber, coffee, nuts, wax, frankincense, myrrh and gum. They possess large flocks, and the trade in hides and skins should be very valuable. There is no doubt that if they had a market for their produce they could send down immense quantities of grain and hides, both of which hardly pay to export by the present expensive and tedious system of caravan. Thus the Juba river is not only in itself an asset of immense value, but it is equally valuable as a cheap and quick means of communication with the only good harbour on the coast. The Somalis themselves will soon grow accustomed to the presence of Europeans, especially when they find that their own prosperity as pastoralists is increased. They seldom now raid the more peaceable inhabitants of the Boran or the Juba valley, but confine themselves to roaming the vast sand stretches which form a

large proportion of Jubaland proper. This inland territory is practically unknown. That it supports a large population of handsome savages who are wealthy in herds of camels, goats, sheep and cattle, is known. All the rest is surmise. It is more than possible that it is in many places well watered, and it must contain large areas which are fertile enough to feed the flocks. One most important fact about Jubaland and its river is the climate, which is both dry and bracing. It is perhaps the most healthy spot in the whole of Central Africa. Mosquitos even on the river are not so troublesome as in other places, and even the dreaded Ts'se fly is only found in the heavy bush and is not spread over the whole district. Snakes are not numerous, and the larger carnivora uncommon. Herds of antelope and buck are frequently seen. The Juba has more than its fair share of crocodile. As a sporting centre there are many places that will give a bigger bag than Jubaland. It is essentially a land for the colonist who understands agriculture, and especially cotton.

The cotton plant prospers in warm, damp climates such as those of Georgia and Louisiana, but thanks to irrigation it is now grown to a great extent in Egypt, where it has proved highly profitable.

In order to mature its pods, the cotton plant needs from 800-1,200 mm. of water. It requires mellow, fertile soil, which is thoroughly tilled and fresh.

Up to the present cotton has been cultivated, not without success, in the Colony of British East Africa, by relying on the rainfall. Many planters, however, on the coast have more than once been disappointed through the irregularity of the rains.

It does not do to be dependant upon the rainfall. Therefore the cotton plant can only be cultivated in a rational manner by laying down a suitable system of canalisation to permit of irrigation. But for this purpose it is necessary to be near a river, and no river in British East Africa could supply the water necessary for irrigation better than the Juba. Generally speaking, the water of the Juba River is very similar in composition to that of the Nile. This is readily understood, as the two rivers both take their source in the neighbourhood of the Lake Victoria Nyanza and on the plateaux of Abyssinia. During the flood season the Juba also carries down a large quantity of mud of an exceedingly fertilising nature, which would be deposited on the land by means of the system of irrigation.

Unfortunately, few of our planters in British East Africa are in a position to thoroughly learn the requirements of the cotton plant, which needs very special care and a vigilant eye.

In Jubaland the first experiments were made on Italian territory, by Mr. Gustave Carpanetti at Torda. The experiment succeeded very well, Mr. Carpanetti having obtained exceptionally fine plants. Shortly after he founded a company at Milan, called the "Società per il Cotone in Somalia." Mr. Carpanetti relied upon the rains,

which in 1907, did not fall, or scarcely at all, and therefore the results which he obtained were mediocre and contradictory to those of his experiments at Torda. This however did not discourage him, and he saw that it was only by means of irrigation that he could arrive at a sure result. On British territory, the only person who has attempted the cultivation of cotton is Mr. G. Argyropoulc, Agricultural Engineer, of the University of Gembloux. He also worked in hopes of the great rains, which, although they are very rare, are nevertheless sufficient to bring the plants to maturity. On 10 hectares (about 20 acres) he obtained a crop of 22,050 lbs. of raw cotton, which makes 2,205 lbs. per hectare, or about 1,100 lbs. per acre. It must be taken into consideration that the work of preparing the soil was done by manual labour, and therefore very incompletely.

After having obtained this result, he decided to acquire a set of tilling machines from Aveling and Porter, Rochester, including two locomotive-ploughs, harrows, ploughs, cultivateurs, &c., and a centrifugal pump of 10 cubic metres capacity per minute. These machines arrived in the Colony a short while since, and are the first of their kind imported up to the present. It would seem that with this plant he is certain to obtain good results, and no doubt in the province of Jubaland we shall soon see lands producing from 1,500 to 2,000 lbs. of raw cotton per acre.

As regards the soil in Jubaland, this may be considered very fertile. The arable soil is exceedingly deep, and as a result of the clearing of the forests the soil is virgin, has undergone no cultivation except at one or two points by the natives, and has a great advantage as compared to the Egyptian soil: *i.e.*, the lack of chloride of sodium, which in Egypt necessitates irrigation known as "washing" before planting is commenced.

Thus, the Province of Jubaland seems to offer very advantageous conditions for cotton cultivation, and moreover the region permits of the establishment of scientific crop rotation between cotton, maize and sesame or beans, all plants which grow very well, and of which the maize and sesame find an immediate market in the country itself. The example of the Italians is stimulating, and it is to be hoped will act as an incentive to British enterprise.

### BUSINESS NOTES.

There has been of late a general advance in the prices of tropical and semi-tropical products, and in all probability this is more or less permanent and bound to go further. Demands are constantly growing, but the producing population remains comparatively stationary in numbers, and therefore the cultivated area responds slowly. Everywhere the cry is for labour, and the pinch is being severely felt in many places. The improvement of the future lies with the increase of labour-saving appliances, and the consolidation or co-operation of enterprises.

One of the very few articles which have not gone up in price is the banana—a curious fact considering that the taste for it in this country has been acquired quite recently, and that the demand has increased enormously here and is now doing so in Germany. Probably the explanation is the facility and quickness with which bananas are produced and collected. The business is just the thing for the average native, and his attentions to it are likely to prevent the price from going up much. Whether it pays the planter is another matter. It must be remembered that places like Costa Rica produce bananas in enormous quantities and are likely to go on doing so. Good profits, in fact, can only be made as a rule on articles which call for work and care.

Cocoa has been brought down in price, after a great rise in 1907-8, by rich yields in Ecuador, Brazil and San Thomé. It will probably go up again. Profits will also be increased in the case of this product by improved methods. The yield differs enormously accordingly to the selection of types and the system of cultivation, and propagation of the best types by budding or grafting will lead to a great increase in this production.

It is not advisable to devote much attention to any article which has not a large market and is in the hands of brokers who do not consider it to their interest to encourage development. Arrowroot is an instance of this kind.

The rise in sugar is no doubt largely attributable to the comparative failure of the beet crop on the continent, a result of an unusually sunless and wet summer. The price excites the hopes of the enthusiast, who see a prospect of a new agricultural industry for the United Kingdom in the shape of beet sugar; but it would go down with a good European season, to say nothing of the by no means remote chance of bad weather here. On the whole the tropical growers have little reason to fear the effects of any such competition.

---

### Rubber.

The unique success which has attended the planting of rubber in Malaya, Ceylon, and other countries, has naturally turned the attention of all interested in tropical agriculture to this cultivation, and no country where the climatic conditions are favourable to the growth of the plants whose rubber is already valued high in the market, would be wise to neglect consideration of rubber planting as an industry which may prove, as it has done in the East, far more profitable than any other agricultural venture.

There is little need to tempt the natural desire of the Tropical agriculturalist by mentioning the profits which have accrued from rubber planting in Malaya and Ceylon. The wonderful results in Malaya are now well known; during the last eight years some fifty million trees, or over 300,000 acres of land, have been planted; many of the estates which are in bearing are paying 100 per cent. per annum on the capital expenditure on the fields which have already come into bearing.

The high cost of agricultural labour necessarily means in some countries the adoption of different methods of cultivation from those of the countries with more favourable labour conditions. The practice which has produced such excellent results in the East of keeping the fields absolutely free from weeds by regular going round every ten days or a fortnight cannot, owing to the prohibitive cost of labour, be carried out here. The methods of tapping *Hevea* which obtain in Malaya and Ceylon require the careful shaving of the cuts on each tapped tree 120-180 times in the year.

Both these methods of rubber cultivation in the East are less suitable in the West Indies and elsewhere, and other methods must be adopted to achieve if possible, equal results. The system of cover plants instead of clean weeding may be adopted as being a method of saving a large proportion of the cost of bringing rubber into production without retarding the growth of the plants cultivated. (*Trinidad Bulletin*).

The decision for intending rubber planters as to which plant may be expected to prove more profitable, depends largely on locality and the seeds available. The chief arguments in favour of *Hevea* are that

it grows vigorously on comparatively poor soils which are well drained. That the yields of rubber from the trees already tapped, as far as they have gone, compare favourably with those of similar age in other countries. That the method of extracting the latex from the Para rubber trees has been brought to a degree of perfection, which, though still capable of improvement is eminently satisfactory and practical. Against this, however is the argument that these methods of extracting the latex from Para involve a large amount of regular daily labour which we cannot hope to reduce by mechanical means.

The rubber of cultivated Para trees has secured a high place on the markets of the world as a valuable rubber, and is in continual demand by the manufacturer. The coagulation is easy and the preparation of dry rubber a well understood and easy process.

The arguments against Para as compared with *Castilloa* are, that the supply of seed locally is limited, and importing them from the far East is by no means an easy or certain way of getting plants, and that the plant when young is greedily eaten by almost all animals.

A system of communal rubber plantation has been inaugurated in the Central Province, Southern Nigeria, and it is proposed that the Government should collect the produce and ship it to England for sale. The plan is capable of great development, and it will be interesting to see how it progresses.

In some tests that have been applied lately in the Straits Settlements the latex ran best from the *Hevea Brasiliensis*, and the dry rubber had the following composition:—

				per cent.
Rubber	...	...	...	98.14
Resin	...	...	...	1.86

In the case of the *Landolphia Heudelotii* the figures were:—

Rubber	...	...	...	89.50
Resin	...	...	...	10.50

Other examinations have given a percentage of 86.6 of dry rubber from the *Funturnia Elastica* from Sierra Leone, and of 90.5 in another case of *Funturnia Landolphia* rubber from West Africa showed results rather inferior to those attained in the East.

A great number of native rubbers are under examination, but many suffer from improper preparation. Mouldiness is a sign of this. A considerable amount of resin greatly diminishes the elasticity, and can generally be detected by a moist appearance.

Some investigations as to the yield of latex are described in Bulletin 19 of the Hawaii Agricultural Experiment Station, entitled *Experiments in Tapping Ceara Rubber Trees*. The first trial was

made with eighty trees, which averaged  $13\frac{1}{2}$  inches in circumference at 3 feet from the ground, and were 23 feet in height; the first branches were at 10 feet from the ground. The trees were tapped by means of one vertical cut each day, and nearly 37 hours of labour were required for tapping them, collecting the latex, and obtaining, by coagulation,  $1\frac{1}{2}$  lbs. of dry rubber. It was found that four ordinary Japanese labourers, who had had no previous experience of the work, could tap eighty trees in a period which varied between seventeen and forty minutes.

In a second lot of trees, which numbered 160 in this case, two vertical cuts were made instead of one, and it only required forty hours of labour to tap the trees, collect the latex, and obtain  $7\frac{1}{2}$  lbs. of rubber, of which  $2\frac{1}{2}$  lbs. was scrap. The experiment showed that with the prices which obtained for rubber at the end of 1909, when two vertical cuts were made daily, profitable returns were obtained from two-year-old trees. It has to be considered that the labour of tapping small trees is greater than that of dealing in the same way with large ones, and that the yield of latex is much lower, so that, with the same amount of labour, more rubber would have been obtained from older trees.

It was found, during the experiments, that one labourer can tap about fifty trees in an hour, while the latex produced by the work of two such labourers can be collected by one. Subsequent experiments with mature Ceara rubber trees have shown that about  $\frac{1}{3}$ -oz. of dry rubber may be obtained as a daily yield from each tree. This leads to the conclusion that three men should be able to obtain rubber from mature trees at the rate of about 1 lb. per hour.

In the matter of the relation between the size of the tree and the amount of tapping that can be effected, it was found that the area of bark on plants 4 inches in diameter will permit of tapping, with one vertical cut daily, for two successful weeks, or with two vertical cuts every day for one week. Larger trees would, of course, permit of the collection of latex for a much longer period.

---

The *Journal d'Agriculture Tropicale* contains, in a recent number, an account of a method known as the Purub process for coagulating the latex of *Hevea brasiliensis*. Purub is a contraction of the words "pure rubber," and is an invention brought out by Dr. Sandmann.

The process consists in the addition of water to the fresh latex, to which, after a fine cloth has been passed through it, there is added a solution of Purub of 1 per cent. strength, the mixture being stirred. After this has been allowed to stand for several hours, the rubber, which has collected on the surface, is skimmed off, and as much of the water pressed out of it as possible. Prepared in this way, it is soon ready for despatch from the estate

The active agent in the coagulation is hydrofluoric acid. This may be replaced by a 10-per cent. solution of hydrofluosilicic acid at the rate of 5 c.c. of the solution to each litre of the raw latex. The acid salts of these acids, such as potassium and sodium fluoride, potassium, sodium or zinc silicofluorides, either in the solid state or in solution, may be employed for the purpose.

The chief advantage of this process is to reduce considerably the amount of impurities in the rubber; these are retained to a great extent by the settlement of the heavier among them during the process of coagulation. In addition to this, hydrofluoric acid, being an antiseptic body, kills all putrefactive germs; rubber prepared by its aid never becomes viscous. Smoked rubber possesses this characteristic as well, but the smoking process adds impurities to it, and makes it black in colour. In the Purub process, this is all avoided, and there are the additional advantages that it is more speedy and requires less labour. There are other advantages, too, in that all injurious organisms are destroyed, even in the interior of the coagulated mass, and there is no need to dry the rubber—a fact that is in accordance with Bamber's opinion, that rubber is better for a water content of 9 to 10 per cent. (*West Indian Agricultural News.*)

---

### Cotton.

The American crop will probably be short this year, but it must be remembered that the price is affected much more by increasing demand than by such shortage. In 1895 the world's spindles numbered 94 millions and last year there were 129. It is clear that a great extension of cotton cultivation will be required to keep pace with the demand, and it is not likely to take place in the United States when the high price of food-stuffs will tend to reduce the cotton acreage. It seems likely that South Africa will be a supplier. The British South Africa Company have taken 5,000 shares of the British Cotton Growing Association, and the low veld farmers of the Transvaal may take up the enterprise. Cotton in such places has considerable advantages. It is not eaten by locusts. They only damage it if they settle on it in immense numbers, when they may break the branches. Once established, it takes less harm from hail or drought than other crops, and when full grown revels in tropical heat, provided it is kept well mulched. It can be stored after ginning without the fear of damage by Angoumois moth, weevil or mice, and be kept for a rise in the market if necessary.

Best of all, it can be sent to a market where one is sure of a ready sale at a price proportionate to the quality. It thus encourages the grower to produce good staple and quality, in the knowledge and certainty that such will bring its own reward by fetching a good price.

On the other hand there is a peculiar treachery in cotton which makes it necessary to experiment carefully in order to ascertain what varieties are suitable for the soil. It should be remembered that the attempts to grow American, Egyptian and Bourbon cotton in British India have generally failed. Selection must, therefore, be practised and results watched before anything is done on a large scale.

---

### Oilfields.

The only wonder about the oil boom is that it has not come before. The western plains of the United States produce every year a value in oil equal to that of the Transvaal output of gold, and the luck of a finder has long been a byword; now that new uses are being found for the product the demand is greater and the search keener. The difficulty is that geological characteristics are in themselves of little practical use to the explorer. Oil and gas are widespread in the earth, but they only become concentrated when strata have been crushed and folded into "anticlines" and "synclines"; in such places, having a light density, they tend to rise, while water descends, but it is not every anticline that yields oil. The explorer looks out for some actual manifestation of the presence of oil, such as a natural issue of gas or bituminous rocks. There must be beds of sand which can store the oil and of clay to prevent its escape. Such conditions are plentiful in Trinidad, where there is reason to believe that there are 500 square miles of oil-bearing land, if not more. It is to be hoped that the labours of Mr. R. Rust in this colony and of the Hon. A. Ponsonby in Barbados will be rewarded, especially as this is conceivably a case where the gain of the individual will be shared by the Empire. This consideration will no doubt be borne in mind when questions of royalty or rent are under review.

---

The growing importance of oil lends special interest at present to any well-reasoned account of operations, and a report on the Taranaki Oilfield, New Zealand, by Mr. J. M. Bell, Director of the Geological Survey, is well worth study. Mr. Bell states that, up to the present, success can hardly be said to have been attained in the Taranaki Oilfield, and the question arises, what are the chances for the future? So many attempts have been made to obtain a payable well at Moturoa that one would naturally feel discouraged for the future were it not that in the writer's opinion a fairly definite reason can be given for the failures. Away from Moturoa drilling can scarcely be said to have yet been prosecuted sufficiently to properly test the field.

There can be no doubt that there are abundant surface indications. Petroleum-seepages have been actually seen by Mr. Bell only at Moturoa, though they have been reported from the Waitara River

and elsewhere. Natural gas is widespread. Wherever this occurs in quantity there is a strong probability that it has ascended vertically from porous strata below, which very likely—but not certainly—contain the other product of distillation of carbonaceous material—namely, petroleum.

As mineral waters nearly always accompany petroleum, mineral springs and the evidence of former mineral springs are to a limited extent favourable indications. Travertine, a deposit of a former mineral spring, occurs at several places in the area, notably at German Hill.

A loose porous stratum, such as a sandstone, a conglomerate, or a limestone, is ordinarily considered the most favourable situation for the occurrence of a large reservoir of petroleum, when this is capped by an impervious stratum such as a shale or a claystone. Interstratified claystones and sandstones have been pierced by the various drill-holes so far sunk; but it may be said that the sandstones, being generally fine-grained and argillaceous, are usually not sufficiently porous to contain much oil. It is thought that most of the small pools so far encountered are either in fissures in both sandstones and claystones, or are very minor impregnations in the more porous of the sandstone beds, and that the oil has arisen through fault-planes (which are widespread in this locality) from reservoirs more deep-seated than those so far pierced by the various bores.

A complete examination of the Tertiary strata so well exposed eastward and northward from Moturoa to the Mokau gives the observer a very fair idea of what may be expected in the drill-holes. Overlying the extensive Mokau coal-beds, the south-westerly extension of which, by coming in contact with volcanic heat or mere increase of heat towards the earth's interior, have been the source of the petroleum, are thick beds of porous green sandstones. It is thought that until these are cut by drilling no very extensive pool of oil will be struck, unless perchance a large fissure rising from great depths is reached above. Consequently it follows that the drill-holes so far put down at Moturoa are not sufficiently deep, and Mr. Bell suggests that one hole be chosen, preferably No. 3 (as being the most westerly and consequently apparently the nearest to the source of oil), and pushed down until the porous stratum seen on the Mokau is encountered. It would be quite hypothetical in the present state of the Geological Survey of the oilfield to say at what depth this stratum will be reached, but it is hoped to obtain more definite knowledge on this point before our work in the locality is complete. Meanwhile the exploratory bore should be proceeding.

In the present state of our knowledge it seems that hopeful petroliferous country, in which boring might later be carried out with success, lies between the present No. 3 bore and the foot of the break-water. Any bores, however, sunk in this locality should await the

results of the deep trial bore—the continuation of No. 3—and when put down should be located at a sufficient distance from the foreshore to be uninfluenced by the sea.

Away from Moturoa all indications must be closely examined and carefully studied before sites for boreholes are chosen. Ordinarily the crest or near the crest of a faulted anticlinal fold is considered the most hopeful site for boring. To such a natural apex the oil would readily ascend through the faults till a porous stratum was reached, from which stratum further migration upward was prevented by an impervious roof.

It is thought that the Geological Survey will be able to reveal, especially towards the east of the field, these anticlinal crests, near which gas now issuing—evidently through fissures—suggests petroleum-pools beneath. However, the work has not yet advanced sufficiently to speak definitely on this point. In the eastern part of the area drilling would probably not necessarily have to be prosecuted to such depths as near Moturoa, since there is a general rise of the strata towards the eastward and northward.

It may be remarked that, even with the greatest attention given to all geological details before selecting a borehole-site, there is danger that the lower part of the petroliferous strata encountered “may contain water instead of gas and oil; or may be calcified or silicified instead of being bitumenized; or that water has entered the outcrop of the strata at higher altitudes [than the borehole-site] and ascended through the formation, floating the oil to the surface and carrying the same to the other dip of the antioline”<sup>\*</sup> than that on which the drill-hole is proceeding.

It is unfortunately true that theory and observations cannot be perfect, but they are immeasurably better than the mere guessing which alone can be said to have accounted for the choice of the sites of many of the Taranaki boreholes.

In Mr. Bell's opinion the chances for oil in Taranaki may in general be said to be as good as in any imperfectly tried field, and it is hoped that after the observations of the Survey are complete the industry will be pushed as vigorously as surface indications certainly seem to warrant.

It has been suggested that oil, tar and gas can be obtained by treating kauri-swamp peats, such as are found in New Zealand.

By “kauri-peat” is meant swamp composed mainly of decayed and decaying kauri vegetable matter, leaves, bark, limbs, roots, &c., and decayed or sugary gum. There are thousands of acres of these swamps north of Auckland, and they are well known to contain large quantities of saleable kauri-gum and kauri-timber lying buried.

---

<sup>\*</sup> See “The Genesis of Petroleum and Asphaltum in California,” by A. S. Cooper Bulletin No. 16, Calif. State Mining Bureau.

It is also a well-known fact to gum-diggers that the best of the kauri-gum lies beneath the kauri-trees buried in these swamps, and, as these swamps run from 4 ft. to 14 ft., more or less, in depth, it is impossible to get out either this valuable timber or the gum by the present system of digging.

It is claimed that the products obtained by heating the material in a cast-iron chamber (oil, tar and gas) would cost not more than 2d. per gallon.

### Valuable Timber.

Much of the West African timber is disappointing, but there is one country—Southern and Western Ashanti—which produces excellent cedar and mahogany and the indigenous rubber tree, *Funtumia Elastica*. The potential supply is enormous. Already the exports from West Africa to Europe and America exceed those from Central America and Cuba, and the trade is sure to grow. At present the Sekondi railway is the only practicable means of export, and the felling must therefore be limited to its neighbourhood, but it would not be very expensive to clean the Tano and other rivers sufficiently to permit logs to float down; these operations need not be so great as in the case of making channels navigable for boats. If this were done the present export could be quadrupled. The following estimate is given by Mr. H. N. Thompson, Conservator of Forests, Southern Nigeria.

“As timber can, under existing conditions, be extracted profitably only if the length of drag from the forest to the nearest stream capable of floating logs does not exceed three miles, that distance may be taken as the extreme width on either side of the floating streams and railways to which exploitation can extend. Again, the proportion of one mahogany and one cedar tree to every five acres may be accepted as a safe figure to go on. It is in all probability rather less than the actual proportion found in the forests. Taking the railways first, the area available for exploitation with human labour as the hauling power is as follows:—

Distance from Sekondi to Kumasi = 168 miles.

„ „ Tarkwa to Preea = 25 „

---

Total = 193 miles.

Consequently exploitable area =  $193 \times 6$  square miles  
= 1,158 square miles.

Deduct 25 % for clearings, farms, &c. = -289 „ „

---

Total = 869 „ „

“ This area at the rate of one mahogany tree for every five acres, or 128 trees to the square mile, will contain  $128 \times 869 = 111,232$  mahogany trees. And as the same number of cedar trees per square mile may also be assumed to exist, the total number of mahoganies and cedars available for felling will be twice the number given for mahogany, or 222,464 trees. Deduct from this 25 per cent. of the trees to provide for unsound, crooked, or otherwise defective trees, and we are left with a balance of  $222,464 - 55,616$ , or 166,848 trees.

“ Now assuming that it takes thirty years for all the trees now between 10 and 12 feet in girth to reach the latter size, then the number of trees (12 feet and over in girth) that should be felled each year amounts to  $\frac{166,848}{30}$  trees, or 5,561 trees, which, on the assumption that one tree yields three logs, amounts to an annual output of 16,683 logs.

“ Similarly the timber from the basins of the Tano, Ankobra, and Pra Rivers may be estimated as follows :—

Exploitable area on Tano and its larger feeders	= 900 square miles.
That on the Ankobra	= 300   "   "
That on the Offin River	= 500   "   "
That on the main Pra River	= 600   "   "
Total	= 2,300   "   "

And the number of mahogany and cedar trees on this area may be computed at  $2,300 \times 128 \times 2$  trees = 588,800 trees. Deducting 25 per cent. for defective trees, the number left for felling amounts to 441,600 trees. Hence, the annual output will equal  $\frac{441,600}{30}$  trees = 14,720 trees or 44,160 logs.

“ Therefore, the total output from both railways and streams should amount to  $(16,683 + 44,160)$  logs = 60,843 logs. The calculation of the output from the streams, however, is based on the assumption that the channels of the Tano and Pra Rivers are opened out to timber exploitation by the removal of the obstructions in them. Unless this is done, the annual output in logs cannot be expected to reach much more than 25,000.

“ Every effort, however, should be made to clear the above-mentioned obstructions and at the same time to introduce mechanical appliances, such as traction engines, light tramways, &c., for the haulage and transport of the timber. When this has been accomplished, the Gold Coast, with Ashanti, should be able, and that without any fear of encroaching on the wood-producing capital, to give an annual yield of something like 250,000 logs a year.

Such an out-turn, even at a very mild rate of taxation, should be capable of bringing in an annual revenue of about £60,000.

“These estimates do not include other first-class timbers such as are yielded by the *Odoum* (*Chlorophora excelsa*), the *Baku* (*Mimusops Djave*), &c., and are based on the most unfavourable assumptions. To my mind the Colony, with Ashanti, has a great future before it, so far as the timber industry is concerned.”

The position is well worth the attention of capital.

---

### Mahogany.

The price of this timber has risen substantially lately. The demand seems to come mostly from America and is likely to continue. The increased value should stimulate the industry in British Honduras and other places which can conveniently supply the United States. The hardwood trade from Australasia will probably share in the improvement.

---

### Forest Concessions.

A concession of about 5,126 acres of forest land in the Nabugulo district, Uganda, has been granted to a company for a term of 21 years at the nominal rent of 10 cents per acre, and a royalty of 5 per cent. on the produce. The company is to plant not less than 10,000 rubber trees yearly. The forestry operations will be under the supervision of the Government. A vast amount of forest awaits exploitation and will no doubt be largely dealt with by such arrangements.

---

### West African Mines.

In the vicinity of some of the mines whole hillsides have been denuded of trees to provide fuel, and whenever an area has been cleared for this purpose, it may be suggested that use should be made of it for rubber and cocoa. The initial expense of clearing, which is the greatest item, has been incurred for another purpose, and the planting would begin with every prospect of economical success and probably yield large profits to the companies. Such planting operation should, however, Mr. Thompson observes in a report on Gold Coast Forests, if they are expected to help towards the protection of the soil against exposure, be undertaken with species with the evergreen habit and not alone with those that drop their leaves in the hottest and driest season of the year, as is unfortunately the case with the Para rubber plant (*Hevea brasiliensis*), one of the quickest growing, hardiest, and best rubber producers known. This species has the deciduous habit most pronounced when growing in localities having a well-marked and prolonged dry season. Nevertheless if grown in mixtures with cocoa (cocoa as the “underwood” and Para as the “overwood”) a sufficient protection should be afforded the soil by the dense shade cast by the latter.

The Para rubber trees are only bare of leaves for a short period each year.

The land at the disposal of the mines is, generally speaking, sufficiently extensive to permit of a long felling rotation, and in consequence the secondary growth has time to reach good dimensions before it is again removed. This is not the case with the farming rotations usually adopted by the natives, who return to the same area in periods varying from three to nine years, and the secondary growth has therefore insufficient time for attaining a large size. Hence, looked at from the worst point of view, the dangers following the cutting of the forests near the mines for firewood are nothing like as great as in the case of the much more extensive areas utilised by the native farmers. Their operations, for the reason indicated above, are much more likely to, and actually do, adversely affect the climate and the soil. If by the discovery of new goldfields the mines become so numerous as to involve extensive and continuous tracts of country, then the consequences of felling in a haphazard manner every year such large blocks of forests would be more serious, and the fellings would have to be regulated by the Government.

#### Motor Transport.

On the Ibadan-Oyo service, Southern Nigeria, the average takings in 1908 were £156 a month, two vans being employed, one a 2-ton Lacre and the other a 3-ton Thornycroft. The advantage in cost and time over hand transport is considerable, to say nothing of the fact that natives, not being required for carrying, can follow agricultural occupations to the benefit of the country, and that goods arrive in good condition.

The use of paraffin effected considerable saving, and it has been well worth the trouble experienced by all concerned. Many different types of paraffin carburetters were tried on the Albion engine before success was attained by the use of the Cottrell vapouriser, but as this fitting proved to be too flimsy and gave considerable trouble, a simple air heating box was designed and cast in one piece to take its place, and this answers the purpose equally well with no possible chance of trouble.

It must be borne in mind that the Albion motors fitted to the Lacre vans are purely petrol engines, but it is recommended that for paraffin the engine should be specially designed—alterations to engines are not desirable and were only made to engines already in use and on order.

A large amount of time and expense has been caused by the wooden artillery pattern wheels continually giving way; every effort has been made to get the makers to supply cast steel ones, but it was not until the latter part of 1908 that they were able to fit them.

The first two vans were fitted with grooved De Nevers solid rubber tyres, and the next two were fitted with Sirdar tyres to the rear wheels, and soft Clinchers to the front; none of these tyres were satisfactory, especially the Sirdar tyres, which after a few hundred miles running started to "creep" and then became detached.

The type of tyre now being used for the vans is the Shrewsbury and Challiner World tyre for the rear wheels, and the Giant type for the front wheels. These tyres are vulcanized to a strong perforated iron band, and they are attached to the wheels by means of strips of wooden lagging driven tightly in. It is not anticipated that there will be any further trouble with such tyres, as the makers are willing to guarantee them for 10,000 miles run, at a price which works out at 1·7 pence per mile for the 2-ton vans.

---

### Gold in Fiji.

A rush is taking place to Fiji, and some 68,000 acres have been applied for for prospecting. Some districts hold out great promise, but no payable alluvial ground had been found by February, and capital would be required for development. Blocks of true andesite are found, and this is one of the most favourable rocks for containing auriferous lodes throughout the world, and at Nasevou several hot springs rise through a fissure in the solid rock, altering it and depositing lime or sinter, thus showing the process by which mineral veins are formed still in operation. The zone of rock in which the hot water rises is leached and altered, and from the silica carried in solution and deposited therein it becomes more and more silicified. Then, if auriferous solutions come into existence at greater depths, particularly after the deposition of iron pyrites in such channels, gold, in its turn, is deposited and becomes a constituent of the *vein* which is truly an *artery* for the hydrothermal circulation in the rocks, and a repository for the dissemination of the precious metals therein.

Mr. N. D. Cochrane, F.G.S., has been engaged by the Government to examine and report on the indications, and has formed a very favourable opinion on the Wainatu-Waivake line of mineral country, where he considers, with adequate prospecting, payable mines should be developed. The gold, more likely than not, will be contained in the iron pyrites and invisible to the eye and lens—much after the manner of the gold-silver ore-bodies at Waihi, in New Zealand, and, probably, like them, richer as greater depth is attained. It is no poor man's field, but will require ample capital for prospecting and development. Much of the success of the field will depend on that condition, together with its efficient and capable expenditure.

At Namosi the dominant rock is volcanic agglomerate on each side of the river, strongly jointed, and rising in nearly vertical cliffs

to great heights, with rugged serrated outlines, forming a magnificent gorge, or pass, unequalled of its kind. This expands until a low saddle is crossed and the watershed of the Navua River is entered, where "soapstones" or tuffaceous mudstones form the flat country at the Waikoroiluva and Navua rivers.

Namosi itself, with its double amphitheatre of rock-bound heights, presents the appearance of a vast crater. Mr. Cochrane considers the rock-cleft Namosi Pass is primarily a great volcanic rent, and that no other agency could account for it.

It seems probable that payable mines will be found, and there are also indications of petroleum—as to this Mr. Cochrane observes:—

"In regard to petroleum: This is a matter which is very speculative, and as to which the most experienced can only give an opinion. The *indications* are usually petroleum "scum" and gas-bubbles. The former occurs at one place only—Namenā—but extended search might, and probably would, disclose others. No gas-bubbles were seen.

"The *conditions* favourable for the occurrence of petroleum and its retention in the strata are (1) an open porous rock-bed as a reservoir; and (2) a more impervious overlying-bed to prevent its escape. Together with a formation of such (3) age and (4) structure as occurs in this district, and (5) one of very considerable thickness.

"Both (1) and (2) may very well, and probably do, occur near the lower part of this formation; but (5) is uncertain, though there are indications which point to its existence. Taking all into consideration, while due allowance must be made for its uncertainty, and comparing with the oil occurrences in Taranaki, New Zealand, I am not unfavourably impressed with the prospects of finding petroleum in this district."

---

### Southern Nigeria.

A new map of the Eastern and Central Provinces has been prepared by Captain Woodroffe and published by Messrs. Stanford. It is on sale at from £1 to £2 according to mounting, and will no doubt be found very useful by the numerous companies and prospectors who are interested in the territory.

---

### Australian Imported Goods.

A return has been published showing the articles which have been imported for the use of Government offices during 1908-9, with the prices paid and in most cases the names of the suppliers. The list represents almost all the articles which are imported into Australia, and the particulars given deserve the commendation of manufacturers and merchants in this country, who will gather from them a clear idea of what is wanted and what competition there is to meet.

## RAILWAY NOTES.

### Ceylon.

It was proposed to adopt the Renard road train, but this idea has been put aside in favour of spending money on the improvement of roads. There are various private associations in the colony who are considering schemes for road motor traction, and a charge on produce carried over roads which have been specially improved for the purpose would be reasonable. The position and the considerations which have led to it are clearly set out in the following extract from Sir H. McCallum's address to the Legislative Council on the subject:—

“Favourable accounts having been received as to the efficiency and the economy of that novel form of mechanical traction which is known as the Renard road train (consisting of a motor and three trailers), the Government sent expert officers to India to be present at the trial of an experimental train at Calcutta on the plains, and at Shillong in the hills. Making allowance for all the difficulties which attended these experiments, the reports received were fairly satisfactory. Two complete trains were therefore ordered from England, on the understanding that the Secretary of State's expert advisers (who are the Mechanical Transport Committee at the War Office) were first to assure him that the system is as efficient and economical as has been represented. On my arrival home I found that the Committee held a contrary opinion, and considered that both the working expenses and depreciation had been under-estimated. After some correspondence it was arranged that the Directors of the Company and the Committee should meet at the War Office, and that I should be present. After some discussion I invited the Company to supply and themselves work the two trains for two years, Government undertaking to carry out all the improvements necessary to the roads, including the strengthening of the bridges. If the trains proved to be satisfactory, and if the anticipations as to working expenses and depreciation were fulfilled, I undertook, subject to the approval of the Secretary of State, that the Government would take

over the trains at the end of the two years. This offer the Company declined.

"I then proposed that if we purchased the trains, the Company should guarantee the Government that with normal traffic and due care these particular charges would not be exceeded during the five years of anticipated life. This they said they were prepared to do, but a letter from them on the subject laid down the impossible condition that we should give the Company a heavy annual premium in consideration of such guarantee. I agreed with the Mechanical Transport Committee that such a condition was absurd, and that we must look for the necessary mechanical traction in other directions. The principle of the Renard road train in making use of the load carried in the trailers is recognized as sound, and the attention of inventors is being given to the use of electricity for the purpose, instead of the present complicated power-absorbing mechanical contrivances. There is nothing, however, yet upon the market.

"Special designs will probably have to be supplied, as I impressed on the Committee that the weight of an axle must in no case exceed four tons, and that three tons would be preferable. Also that the extreme width over all must not exceed 5 feet 6 inches.

"The general policy of the Government will be to encourage private enterprise in this matter of supplying and working motor traction, always provided that the rates per ton mile are moderate and prove satisfactory to those concerned; also that the service is regular and frequent, and conforms to all local requirements. Any system of mechanical traction will entail considerable expenditure in the matter of improving roads and strengthening bridges. This must either be carried out to the satisfaction of the Director of Public Works by the individuals or companies who desire to embark on the enterprise, or, if the Secretary of State approves, will be undertaken by the Government from the loan vote, a small charge being levied on every ton of goods carried to cover interest and sinking fund on the expenditure incurred.

"Where private enterprise is not forthcoming, satisfactory alike to the Government and the public, the Government will be prepared to consider the advisability of running a service as a business proposition. A capital account will be kept covering cost of rolling stock, improvements to roads and strengthening of bridges, garage, quarters, &c. Under working expenses due provision would be made for repairs and depreciation, interest and sinking fund. Assurances of traffic must be forthcoming from those concerned.

"The lines to which attention is proposed to be given are—

- (a) Kandy (Wattegama) to Teldeniya.
- (b) Talawakele to Agrapatanas.
- (c) Hatton to Bogawantalawa and Maskeliya."

These proposals have been approved by the Secretary of State.

**West Africa.**

In two years Lagos will be the terminus of a railway stretching 800 miles into the interior, and in a few years more it will possess a spacious harbour into which the largest ships of the West African trade will enter. A considerable increase of population may therefore be looked for, and in making provision for the first requisite—water—this fact has to be taken into account. In a scheme which has been prepared for the supply of water from Iju Valley allowance is made for an increase from the present population (Lagos and Ebute Metta) of 80,872 to 150,000. The estimated cost is £260,000, and the annual charge, including interest and sinking fund, would be about £18,922. It is to be hoped that finances will admit of the early execution of the scheme and of quicker progress with the harbour. The dredging for the latter works is going on well; 6,000 feet of shore delivery pipes are now on the spot, and probably very successful reclamation work will be accomplished shortly. There has been some delay at the quarry, but the rock-drilling plant is now fully installed and good results should follow soon.

---

**Baro-Kano.**

By the end of 1909 the rails reached the 135th mile. With the approach to the Kaduna the construction of the road to the Bauchi tin mining area claimed attention, and a survey for this purpose North of the Kaduna to Liruci has been recommended. All bridges and culverts as far as Minna were completed, and all preparations made for the heavy bridge work between Minna and the Kaduna. The programme of work for the dry season comprised an ascent of 1,500 feet to the Kaduna water shed from the Bako Valley, crossing a number of lateral valleys. The freight rates are at present from 8d. and 3½d. per ton mile, according to classification. Passenger fares are 3d. per mile first class, and 1d. second; 3rd class booking was held over pending suitable coaching stock. In December, 4,049 passengers were carried. An average of 9,411 labourers have been employed. The survey of the Zungeru link was completed in December.

Baro unfortunately has the reputation of being the most pestilent fly station in the Protectorate, the number of mosquitos and tsetse flies being enormous, but the bush has been cleared for a large area and the pools treated with oil.

The revised estimate of expenditure (not including the Zungeru link) was £1,230,000.

---

**Jebba-Zungeru.**

It was originally decided, in order to keep the cost of construction as low as possible, that this line should be of the "pioneer" type, which involves the acceptance of heavy gradients

and the substitution of steel trestles for bridges of concrete and steel girders, and of corrugated iron pipes for earthenware or concrete pipes or culverts. The cheap work of this description saves some £10,000, but it involves speed restrictions, constant watching, liability to interruption and some early replacements. The question has therefore been raised whether the saving is justified, and it has been decided to maintain the standard grades of one in a hundred outwards and one in eighty inwards on the Jebba-Zungeru line. With steeper grades the cost could be reduced by about £20,000, but at a time when £175,000 is being spent to improve the 125 miles of the Iddo-Ibadan section up to the above standard, it would hardly be justified to adopt a lower standard for the extension.

---

### Gold Coast.

With a view to the construction of a railway from Accra to Coomassie an exploration has been made of the country between Komfrodon and Coomassie, and it seems thereby that a practicable route can be found. The line might be shortened by diverting it to join the Sekondi railway at Bekwai, instead of going straight on to Coomassie, but it is doubtful whether this route is feasible. The extension of the Akwapim line has, however, been given up for the present.

At Accra considerable progress has been made with the block-setting in connection with the extension of the breakwater, and with the iron jetty, the piles of which have been driven into solid rock.

At Seccondée the root wall was completed in February, the foundations being on solid rock. The two temporary slipways are completed and in use.

The completion of the railway to Prestea, which it was hoped would be achieved by the beginning of May, has been delayed by foundation difficulties.

---

### Ceylon.

The Mannar railway work has proceeded satisfactorily; in March four miles of earthwork were finished at Mannar, and at Madawachchi the jungle had been entirely cleared over the first eight miles. It is proposed to negotiate with some of the contractors on the Assam Bengal railway for cutting earth work contracts.

Concrete blocks have been found the most economical material for the station buildings; a number have been made and seem most satisfactory. With a turnout of 50 per day, by machine, they can be made (10 ins. wide) for 12s. 7d. per cubic yard.

---

### Shiré Highland Railway.

The track has been well maintained and is in very good running order. It is interesting to find that the gangers in charge of each

maintenance gang are natives, and these men are doing very well indeed ; they have been promoted from time to time to replace the Indian gangers, who have been thus gradually dispensed with. Trains are running well and the conduct of the traffic appears to be quite satisfactory. 2,000 tons of maize were carried last year, and it is expected that a much greater quantity will be exported this year. The bridges have been recently inspected and probably some further work will be done to improve them.

---

### Uganda.

It has been decided to construct a railway from Jinga to Kakindu at an outside cost of £160,000. Some reasons for this enterprise were referred to in our last number. An estimate of £3,200 a mile allows a metre gauge as on the Uganda railway, and 41 lb. rails. It is to be hoped that eventually a further line will be laid from Mruli to Butiaba on Lake Albert, so as to complete the communication by rail and steamer between Lake Victoria and Lake Albert ; the distance is about 25 per cent. more than that of the line now sanctioned. There is little doubt that the development of East African trade lies in this direction. A great amount of dissatisfaction has been very naturally expressed in Parliament and elsewhere at the poor show made by British shipping on the East African coast, but the root of the difficulty is obviously the paucity of freight, and the proper remedy is to develop the trade by opening up a promising country. A steamship subsidy is by comparison a throwing away of money, and probably little would have been heard of such a suggestion but for the example of Germany. The opening up of the interior will be a real and permanent improvement, and British shipowners will not be slow to compete for the business when there is a substantial amount of it.

It is proposed that the £160,000 should be voted by Parliament and advanced to the Uganda Government as a loan.

---

### Johore State Railway.

Very heavy rains fell in February and the damage done was very considerable. There were numerous slips in embankments and slopes of cuttings, at one part 46 in ten miles ; and the amount of earthwork required to be done in repairs is estimated at 300,000 cubic yards. None of the bridges, however, of which there are 377, were washed away, and there is nothing in the nature of the damage that indicates faulty construction. Such interruptions are likely to occur for some years after construction, but will yearly be less frequent.

---

### Hong-Kong.

In January the lining of the Beacon Hill Tunnel was completed, the last brick being laid by the Governor. The work has been an

exceptionally trying one and it is satisfactory to see the end of it. All tunnels are now completed, but the earthwork south of Beacon Hill has been retarded by the rebuilding of bridges. A contract for the body work and erection of the passenger stock has been placed with the Hong-kong and Whampoa Dock Company.

The British section of the Line will be ready before the Chinese section, and it is proposed to open it, probably in July, to work up local traffic and transport material to the Chinese section.

---

### Speed down Gradients.

The regulations for German branch lines prescribe the speed at which trains may descend gradients, the speed on steep gradients (1 in 25) being limited to the figure at which the number of the axles would exceed 56 per cent. of the total number of the braked axles in the train. It is assumed that the engine and tender use their own brakes.

Beyond certain speeds the friction between brake blocks and wheels rapidly decreases, and this accounts for some accidents. Moreover the friction decreases when the brakes have been on some time; and the friction between block and wheel is greater than between wheel and rail, so that the retarding effect is less when the wheels are skidding than when they are rotating. These considerations indicate the danger of relying on the brakes to check excessive speed. If an accident takes place the wheels should be examined to see whether they have been worn by skidding.

---

### The Stoats Nest Railway Accident.

This accident between Brighton and Victoria has been the principal subject of recent railway discussion, and the report makes the cause clear. A wheel of the coach had shifted 1 inch outwardly on the axle. It is the practice to force the wheels on to the axle with a pressure of 60 tons, and it appears that this had been done to the satisfaction of the Railway Company's Inspector, but his report of the test could not be found. The moral for all railways is that the inspector should himself see that the wheels are driven home with the required pressure. There is an automatic apparatus which marks on a tape the pressure required during the whole operation, and this should always be used and watched.

---

### Ticket Printing Machines.

The Central South African Railways have purchased three "Regina" machines for experimental purposes.

This machine is in use at Cologne Station, on the German State Railways, where it has earned an enviable reputation for the manner in which it has lightened the work of booking clerks, and enabled a heavy passenger traffic to be handled with greater expedition

than under the old system of printed tickets. The average number of tickets issued per machine at Cologne is 250 per hour, whilst at pressure a far greater number can be dealt with. The advantages of the appliance do not end here. In addition to printing the tickets, the issues are simultaneously automatically recorded, and the fare paid noted on a duplicate register, so that all a booking clerk has to do before going off duty is to total the register slip and count his cash, when, if the day's transactions have been accurately made, the two should at once balance. Should, however, the results differ, the clerk can instantly ascertain if an error has been made, since there can be no question of the accuracy of the mechanical record.

Compactness is a feature of the machine, which is unpretentious in appearance, and of the following dimensions, *i.e.*: 4 ft. in height, 3 ft. 6 in. in length, and 1 ft. 11 in. in breadth. It will carry sufficient plates for printing 2,000 different tickets. The advantage of such a large number of tickets being available in such compact form, and always at hand, need not be enlarged upon.

The working parts of the machine comprise a series of troughs, in which are contained small printing plates, corresponding to the tickets to be issued. The plates are locked in the machine, and can only be printed from by means of a mechanical printing carriage, hereafter described.

At the back of the machine, upon an octagonal drum, is carried an indicator, on which is printed in alphabetical order the name of every station for which printed plates are provided. By means of a movable carriage, somewhat similar in principle to the carriage of a typewriter, the machine is set for a particular ticket required, which is indicated by a pointer attached to the carriage. An entirely blank and valueless piece of cardboard, of the usual ticket size, is then inserted in a slot in the carriage, when by the depression of a small lever a completely-printed and dated ticket drops into a tray provided for its reception. By this one movement the ticket has been printed, numbered, dated, and recorded upon two separate registers—one of which constitutes the clerk's record for remittance purposes, whilst the other is available to the audit office only. In addition to the record, the issue has also been classified in such a manner as will enable statistics to be taken out if required. The responsibility for issues is fixed by means of a "control ticket." This ticket is printed and recorded on the machine by each clerk upon assuming or going off duty, endorsed with the time of taking charge of and handing over the machine, signed, and retained for future reference.

The experiment will doubtless be watched with interest, as in the event of its success the character of the work in booking offices will undergo a change, the result of which will be to lighten the duties by the almost entire elimination of bookkeeping in connection with passenger traffic. (*South Africa Railway Magazine.*)

## MEDICAL NOTES.

## Pellagra.

It appears from an announcement published in *The Times* of May 14th that the Field Commission studying Pellagra in Italy has come to the conclusion that the theory ascribing the disease to the consumption of diseased maize must be abandoned. The investigations of the commission are said to support Dr. Sambon's contention, advanced some years ago, that Pellagra is due to a parasitic infection having probably a definitive or intermediate host. This host is now stated to be the *Simulium reptans*, a species of "sandfly," which is widely prevalent in Italy. It is hoped that the announcement will be borne out by well-considered proofs.

That maize is not the cause of Pellagra is a belief that is gaining several important adherents, among others Professor Alessandrini, of Rome, who has urged upon his students that the disease might be of parasitic origin. Dr. Sambon is at present engaged in the study of Pellagra from the epidemiological point of view, a step rendered imperative owing to the difficulty of obtaining exact records of the presence and prevalence of Pellagra in its reputed haunts. It is therefore necessary for the commission to visit many centres where the disease, especially at this season of the year, prevails in Italy and elsewhere. To accomplish this task a considerable amount of money must be expended, and it would be regrettable if it became necessary to recall the commission prematurely. Moreover, it is not in Italy alone that this important study should be prosecuted, but in other countries where the scourge of Pellagra has appeared. Several letters from other countries adjacent to Italy have been received requesting that the Field Commission should pay them a visit. The Committee would gladly assent were the means forthcoming. Generous donations from several well-known firms and private individuals have enabled the committee to keep the commission in the field up to the present time, but further sums are necessary if the work is to be carried on.

**Yellow Fever in West Africa.**

The appearance of yellow fever on the west coast of Africa has naturally occasioned much anxiety, but the occurrence is fortunately not so serious to-day as it would once have been. The disease has lost none of its deadliness, but the method of infection through the bite of the *Stegomyia fasciata* is now accurately known, and, by the prompt isolation of infected persons, it is possible to reduce the danger of a spread of the disease to a minimum. West Africa possesses a highly skilled medical service, thoroughly competent to deal with an emergency, and they will enjoy the advantage of the advice and assistance of Sir Rubert Boyce, the greatest living authority on yellow fever, who has previously rendered invaluable service in connection with outbreaks at New Orleans and in British Honduras. The latest advices indicate that the outbreak has been confined within narrow limits.

---

**Sleeping Sickness.**

The Sleeping Sickness Bureau has issued Nos. 16 and 17 of its Bulletin, a Subject Index to the Bibliography of Trypanosomiasis, and a revised edition of the valuable little pamphlet containing instructions for the avoidance of infection for the use of travellers and residents in tropical Africa.

## REVIEWS AND NOTICES.

The Report of the Committee on Distressed Colonial and Indian subjects, over which Sir Owen Philipps presided, has been presented to Parliament. The Committee make a number of detailed recommendations, of which the following are perhaps the most important :—

That masters of vessels (British or foreign) when engaging Eurasians and East Indians on European articles at ports in India should be required to give an undertaking to repatriate them, if the voyage terminates elsewhere than in British India.

That an undertaking to repatriate should also be given when native seamen belonging to the Crown Colonies and Protectorates are signed on at the ports of these Colonies and Protectorates (except in the case of West Indian seamen engaged for voyages terminating elsewhere in the West Indies).

That native seamen signing on in the West Indies should be given a special certificate, showing the place to which they belong, so that, should occasion arise, repatriation to the proper Colony may be effected without difficulty.

That it should be made unlawful in the Crown Colonies and Protectorates for natives to leave for the purpose of spectacular performances unless provision is made for repatriating them.

That a special home should be established to deal with distressed West Indians, and that the Strangers' Home for Asiatics should undertake the supervision of it.

That steps should be taken where possible to make known in the Dominions, Colonies, and Protectorates the risk involved in coming to the United Kingdom in search of work unless those who come have means available to take them home if they are not successful.

**The Handbook of Nyasaland** : 2nd edition. (*Wyman & Sons*: 3s.)

This gives a very full description of the Protectorate, and practical advice is given as to the cultivation of the principal products. Land is cheap and labour plentiful, and planters have the choice of a large variety of products. A beginning has been made with Para rubber (*Hevea brasiliensis*). Early in 1906 a Wardian case was received from Ceylon by the African Lakes Corporation containing 2,000 Para seedlings. Of this consignment 266 plants survived and are doing very well, some of the trees being as much as 12 feet in height in July, 1908. In January, 1907, the same trees were only five feet high, and the further growth is regarded as very satisfactory. None of the plants up to the present have shown any signs of disease. In January, 1907, a further consignment of six Wardian cases was received. When despatched from Ceylon these cases contained 6,000 seeds, but only some 2,500 survived the journey, and were planted out at 20 ft. by 20 ft. Of these about 1,600 are alive and doing well, the large percentage of deaths being due principally to white ants and the grub of the cockchafer. To get rid of the latter pest a mixture consisting of one pound of Paris green and three pounds of salt to 40 pounds of donkey manure was used and proved effectual, when dibbled in some little distance from the roots at time of planting. With Para the best results have been obtained on good *dambo* land, well drained; the danger of the plants being killed by the two pests mentioned is very much less on such ground than on the drier and lighter red soil. If the present rate of growth be maintained, tapping operations ought to commence by 1911, and the trees may be expected to flower this year.

Nyasaland cotton has established a first class reputation, but for a great extension of the industry the extension of the railway from Blantyre to Lake Nyasa, so as to take the district with the largest population, is necessary. There are no ginneries north of Zomba, and the expense of transporting seed cotton by native carriers from the Lake districts to the ginneries and thence by rail and river to the coast makes it impossible to export profitably the crop from outlying districts, even when paying only  $\frac{3}{4}$ d. per lb. for seed cotton. This gives the native little encouragement or compensation for his work, and therefore he only produces sufficient to pay his Hut Tax. If the Baro-Kano railway in Northern Nigeria succeed in developing a great cotton production, this would no doubt prove a strong argument in favour of similar enterprise in Nyasaland.

It is stated (p. 225) that recruitment of labour for service outside the Protectorate is forbidden. But numbers of Nyasaland natives have succeeded in finding their way to the Witwatersrand mines, and the Government has found it necessary to recognise this emigration in order to limit it and bring it under control.

**British Honduras and its Resources.** By WILFRED COLLET, C.M.G. (*West Indian Committee Rooms, price 6d.*)

This is a print of a lecture delivered under the auspices of the West India Committee by the Colonial Secretary of British Honduras, and issued to call attention to the immense though undeveloped resources of the Colony. The first question which capitalists put about such places is, What is the supply of labour? and unfortunately in this case the answer is unsatisfactory. The country abounds with possibilities, but it suffers from want of population. All the available labour is absorbed by existing industries, and some means of importation must be devised before any great development is possible; land is cheap and plentiful, and companies growing bananas, cocoa-nuts or rubber on a substantial scale could offer inducements to the natives of better populated places in the West Indies.

---

#### **Bulletin of the Imperial Institute.**

The last issue contains analyses of Sierra Leone rubber samples, which give very satisfactory results. These indigenous plants should in these days of rubber exploitation receive attention, but of course some care must be shown in the selection of areas, and it is much to be regretted that in the hurry to form companies this has not been done in certain West African cases. The great resources of the Colony in palm oil might well be studied as well by investors; it cannot surely be long before the services of the railway in opening up palm districts are taken advantage of on a substantial scale. A simple machine (the Creltin) for cracking the nuts has recently been brought out and should stimulate the industry.

Articles are given on the preparation of beeswax, varnishes and the soy bean.

---

#### **Travel and Exploration.**

The notes on outfit and health preservation are continued in the May number and are very readable, though opinions differ about many details. A great nuisance and danger is removable if it is correct that "Muscatol is a popular preventive of mosquito bites, and now generally replaces the time-honoured treatment of mustard oil or eucalyptus oil. It has the great advantage of being fully as efficacious as these well-known remedies without being 'messy' and unpleasant in its application. By adding a little Izal solution in the bath a traveller is, however, practically rendered immune from the bites of these troublesome insects." Another article, however, on Eastern Travel is not so sanguine about this.

“Insecticides are no doubt considered a prime necessity in Far Eastern travel, but without denying that there may be preparations fatal to insects which consume them in sufficient quantity, my experience of immediate effect of several specifics is that they give the preying insect a greater appetite for human blood and increase his activity! If you coat the parts of your skin exposed to mosquitoes with a compound of Stockholm tar and petroleum, or naphtha, it will take the insects some time to reach through the viscous mess to you. Better wear a veil; but in a fly country, bitten you will be. Treat the bite or sting with ammonia, or lanesine. Eucalyptus oil may be tried as a preventive and palliative.”

---

We have received from Mauritius the first four numbers of *Le Bulletin Agricole*, which is published “sous le patronage de la Chambre d’Agriculture, sans en être l’organe officiel, et a le même caractère vis-à-vis d’elle que le *Colonial Office Journal* vis-à-vis du Ministère des Colonies.” The Bulletin is published monthly, and the subscription is 6 rupees a year; it gives promise of being a useful and practical periodical.

## COLONIAL STAMPS.

BRITISH HONDURAS.—The stock of Victorian stamps remaining in the hands of the Crown Agents for the Colonies on the 30th November last has been destroyed.

CEYLON.—Of the values mentioned in our last issue, the following have been despatched, viz., 10, 25 and 50 cents, and 1, 2, 5 and 10 rupees. The plates for the 2, 3 and 5 cent. stamps have been countermanded owing to the King's death.

DOMINICA.—1/- stamps have been supplied for the first time in the new colour.

FIJI.—½d. stamps have been supplied for the first time in singly fugitive ink, and the 5/- and £1 stamps in the new colours.

JAMAICA.—3d. and 6d. stamps have been supplied on surfaced paper and in doubly fugitive ink, and a supply of 2½d., 4d., 1s. and 2s. stamps in the new colours. The 3d., 4d., 6d., 1s. and 2s. stamps are still of the Queen's head design.

MALTA.—2d., 4½d, 5d., 1s. and 5s. stamps in the new colours have been ordered, this being the first supply of 5s. stamps printed from the plate showing the portrait of the late King.

The 4½d. and 5d. stamps, being printed in one colour by the steel plate process, will be in the colours given in the scheme for this process in our number for January last.

NORTHERN NIGERIA.—2d., 2½d., 5d., 6d., 1s., 2s. 6d., and 10s. stamps have been supplied in the new colours.

ST. KITTS.—1s. stamps have been supplied for the first time on surfaced paper.

TURKS ISLANDS.—A new ¼d. stamp has been supplied. The design is a representation of the *Melocactus Communis*, or Turk's Head, printed in one colour—crimson lake—by the steel plate process.

## RECENT TRANSFERS AND PROMOTIONS MADE BY THE SECRETARY OF STATE.

- Major A. ESSEX CAPELL, D.S.O. (late Inspector, South African Constabulary), Chief of Police, Grenada.
- Mr. P. N. H. JONES, A.M.I.C.E. (Assistant Director of Public Works, Hong Kong), Director of Public Works, Gold Coast.
- Lieutenant F. W. BELL, V.C. (Assistant Political Officer, Somaliland), Assistant Resident, Northern Nigeria.
- Mr. H. A. DANIELL (District Officer, Somaliland), Assistant District Commissioner, Uganda.
- Dr. P. J. KELLY (Medical Officer, West African Medical Staff), Medical Officer, Hong Kong.
- Mr. J. C. D. FENN (late Senior Assistant Treasurer, Gold Coast), Accountant in Treasury, Cyprus.
- Mr. R. W. TAYLOR (Head Accountant in Treasury, Somaliland), Treasury Assistant, Uganda.
- Mr. T. B. BRACKEN (Assistant Superintendent of Police, Gambia), Assistant Commissioner of Police, Southern Nigeria.
- Mr. A. H. HODGES (late of the Department of Posts and Telegraphs, Orange River Colony), Assistant Postmaster-General, Northern Nigeria.
- Mr. M. L. SKINNER (late of South African Constabulary), Assistant Inspector of Police, Uganda.
- Mr. M. ST. C. THOM (Assistant to Finger Print Expert, Orange River Colony), Assistant Inspector of Police, Uganda.
- Mr. W. P. HARRAGIN (late of Transvaal Civil Service), Assistant Inspector of Police, Uganda.

## OFFICIALS ON LEAVE OF ABSENCE IN THIS COUNTRY WITH DATE OF EXPIRATION OF LEAVE.

—

This List is compiled from the Leave Certificates sent to the Crown Agents for the Colonies. The Editors will be glad to receive notice of any other cases of Colonial Officials on Long Leave.

EDITORIAL NOTES.

THE British General Election of this year and the subsequent Parliamentary proceedings have attracted an unusual degree of interest in the Dominions. The main issues were not merely domestic, but appealed strongly to commercial and constitutional feelings overseas. Especially in Canada the struggle produced a ferment of controversy to which there has been no parallel on the like occasions. The *Canadian Annual Review* gives a lively picture of the situation:—

“The preliminary struggle was watched through the clouded glasses of a partisan cable service and of American news agencies, with their naturally Radical tendencies, catering to feelings which had no experience of hereditary legislators and land-owning classes, or of the traditions and social sympathies, obligations and peculiar conditions of the British system. Upon the Tariff Reform issue there had been no distinct party cleavage in Canada, and such tendency as there was had been held in check by the obvious benefits of a British Preference to its people. The issues raised, however, upon the Liberal side in England by the rejection of the Budget produced in Canada an immediate response from the Liberal Press of the country. There was no doubt where it stood in the matter. Papers such as the *Toronto Globe* and *Star*, the *Montreal Herald* and the *Winnipeg Free*

*Press* ranged themselves immediately upon the side of the British Government, and what was termed 'the people' as against the aristocracy and the classes. All the Liberal and Radical catchwords of Britain were used, and their arguments, whether strong or weak, were pressed home; Mr. Lloyd-George and Mr. Winston Churchill were pictured as the popular heroes in a struggle against monopoly and selfish landlordism; Tariff Reform was waived aside as no longer a great and vital issue. The Conservative press was divided. What might be termed a Radical Conservatism evolved—in many quarters—a sort of mixed policy of protection and preference for Great Britain, and of clipping, also, the powers of the House of Lords. Papers such as the *Toronto Mail and Empire* and the *Montreal Star*, which, editorially, defended the Unionist position, gave in their news columns both sides of the question, and other Conservative papers followed suit.

"The Liberal press was, however, aggressive and united in its advocacy. The *Toronto Globe* sent Mr. Stewart Lyon, a Radical of deep-rooted personal conviction, as its special correspondent to London, and Dr. J. A. Macdonald, its Editor-in-Chief, wrote a series of pen pictures of British leaders which, while clever and of great interest, were obviously and clearly coloured by party convictions. Editorially this paper's attitude may be understood from two quotations. On Oct. 9 the *Globe* expressed surprise at the Conservative press for supporting the cause espoused by Mr. Balfour, Lord Rosebery and the Marquess of Lansdowne: 'The point of view of the gentlemen named is not difficult to understand. They have breathed the atmosphere of privilege from the cradle up, but why a newspaper published in this land, whose basic principle is social equality, should be throwing up its cap for the Lords and getting red in the face in defence of their exemptions from the burdens that other men have to bear, defies explanation.' As to Tariff Reform, it would mean a duty upon Canadian agricultural products and the accompanying preference would not be of much advantage. Once established the British tariff would grow in height, and then a new issue would develop: 'The manufacturer will ask for a larger preference for his goods in the Canadian markets than he now gets. The Canadian farmer will join the British manufacturer in this agitation, for he will be drawn by two prospective benefits—easier access for his products to the English market and cheaper goods at home.' The announcement (Dec. 6th) regarding Mr. Lyon's mission stated that the struggle to be described by him was 'a fight to the death between Ancient Privilege and Modern Ideas.'

"The *Edmonton Bulletin*, the organ of Mr. Oliver, Minister of the Interior, declared on Nov. 22nd that a cash subsidy from

Canada to the Imperial Navy would simply be 'a donation for the relief of distressed dukes.' Let the 10,000 people who really owned England be properly taxed, and Canada would not need to give a defence contribution! Late in December Sir Wilfrid Laurier was described by the *Manchester Guardian* (Radical) as having expressed himself in favour of the Liberal cause, and, though the interview was promptly repudiated, the paper followed it up with another alleged interview with an unnamed Canadian Minister, who abused Lord Lansdowne, and ridiculed the Tariff Reform movement. This was resented by the *Standard*, which on Dec. 22nd, said: 'British statesmen on both sides of politics always observe the most careful abstinence from participation in Canadian internal politics. It is incredible that Sir Wilfrid or any of his colleagues would desire to depart from this wholesome principle. Each country must consume its own political smoke.' The Canadian Premier's response was a cable to Lord Strathcona in the following terms: 'I find by Press reports that my name is used in reference to the present political contest. It is well known in this country that I am never interviewed. I have not in this instance departed from this rule, and have had no interview with anyone. If I had any opinion to express on the present contest I would claim the privilege of doing it in my own words, but I would consider it absolutely out of place for me to say or do anything which might be considered, ever so remotely, as an interference in any party contest now before the electors of Great Britain and Ireland.' As to one element in the contest, Mr. Rudolphe Lemieux, Postmaster-General, expressed himself strongly on his return from England. He had been present at the debate on the Lansdowne amendment, and declared to the *Toronto Star* correspondent on Dec 18 that the House of Lords, 'instead of being a decrepit lot of men, represented the greatest aggregation of intellect, wealth and oratory the world has ever seen.'"

The elections for the first South African Parliament have resulted in a surprise. The Government obtains a majority, but it is smaller than had been expected. The Unionists have achieved striking successes in the Cape peninsula, on the Rand, and elsewhere. All their leading men have been returned, with the exception of Mr. Abe Bailey, who was found, after a recount, to have been defeated by Mr. J. W. S. Langermann; while three of the Ministers—Mr. Moor, the late Prime Minister of Natal, Mr. Hull, the Treasurer, and General Botha himself—have suffered defeat. The attitude of some of the Independent members, notably those from Natal, remains uncertain, but the Government's normal majority can hardly be less than twelve,

and will probably prove to be larger. In a comparatively small legislature such a majority is large enough for most practical purposes, but certain special considerations affecting the Government's position have to be borne in mind. Mr. Merriman, who is expected to carry with him the votes of some eight other members, and whose ability and experience render him one of the greatest living forces in South African politics, has taken up the attitude of a candid friend, and it remains to be seen whether his candour or his friendliness will prove to be the stronger. In any case, the Government will need to walk warily. Mr. Hull is credited with a desire to retire from politics, and the provision of a seat for Mr. Moor will present serious difficulties. It was at first rumoured that General Botha himself had decided to retire, but he has resolved to retain office, and a seat will readily be found for him, though he will presumably not be a member of the legislature when it is formally opened by the Duke of Connaught. His rejection by the electors of Pretoria is a serious blow, but it cannot be regarded as altogether surprising. He had chosen to oppose one of the ablest and most popular of the Progressive leaders in a seat where the latter had gained a remarkable triumph over Sir Richard Solomon at the first Transvaal elections. No one except General Botha could have had the smallest chance of displacing Sir Percy Fitzpatrick, and the task has proved to be beyond even his capacity. General Botha's retirement from politics at this juncture would have been, as his opponents have been among the first to recognize, a disaster to South Africa, and we congratulate him on a courageous and public-spirited decision.

From the telegraphed reports of the Budget speech delivered by Mr. Fisher, the Commonwealth Prime Minister and Treasurer, it appears that he made certain announcements of considerable importance with regard to the general policy of his ministry. There is to be a referendum with a view to an alteration of the Constitution, which will give to the Commonwealth legislative powers equal to those of the States, for the settlement and prevention of trade disputes; and a Bill has since been introduced, giving the widest possible extension to the general powers of the Commonwealth Parliament with regard to industrial legislation, which decisions of the Federal Supreme Court have tended to restrict within limits which are by no means to the taste of the Australian Labour Party. There is every probability that the electorate will show itself willing to confer upon the Commonwealth the increased powers which Mr. Fisher seeks to obtain for it. The Government also proposes to take over and develop the Northern Territory, and is

prepared to face a large expenditure on this account. This is a task which admittedly exceeds the present resources of South Australia, and it has frequently been pointed out that the interests involved in it are Commonwealth rather than State interests. The whole of the "White Australia" policy is in fact at stake in the question of the Northern Territory. It is proposed to establish penny postage throughout Australia on May 1st next, and the State debts are to be taken over at an early date. It will be seen that in all these matters effect is to be given to the policy of increasing the powers and responsibilities of the Commonwealth Government, which was the principal feature in the programme upon which the Labour Party won the last election. Mr. Fisher also announced that newcomers of European descent would be heartily welcomed to Australia, and though it would be rash to base great expectations on a telegraphed report of a statement so general in its terms, this may perhaps indicate an intention to embark on an active immigration policy. Labour organizations in Australia have generally been disposed to view such a policy with suspicion, but there is now a general recognition of the urgent need of increased population if the great resources of the Commonwealth are to be properly developed.

---

The Commonwealth Government has published a return of much interest relating to the cane sugar industry in Australia. From this it appears that the policy of substituting white for black labour in the cultivation of this product has been very effectually carried out. In Queensland white labour has to its credit 93½ per cent. of the cane farmers, 92·9 per cent. of the area under cultivation, and 91·7 per cent. of the sugar produced. New South Wales, with smaller figures, shows almost exactly the same proportion, the respective percentages being 93, 93·6 and 94·5. The significance of the Queensland figures will be better appreciated when it is added that in 1902 white labour was responsible for only 15·7 per cent. of the sugar produced in that State. During the same period the quantity of sugar produced has increased from 77,835 to 186,176 tons. The number of persons employed in the industry has also increased, but not so largely, a circumstance presumably attributable either to the greater efficiency of white labour, or to improvements in the methods of cultivation. These figures show that the "White Australia" policy has proved itself practicable in the sphere which seemed to present the gravest difficulties; but the result has not been achieved without substantial cost. The amount of bounty paid in Queensland has increased from £24,493 in 1902 to £531,963 in 1910, and, as this is paid from Federal funds, the greater part of the cost actually falls on New South Wales and Victoria.

Another table, however, shows that the excise duty collected still exceeds the bounty paid, and the expenses connected with its payment by £97,425, though the margin is steadily decreasing. But Australia has generally shown herself ready enough to pay for a policy which she conceives to be vital to her national interests.

---

Sir Newton Moore has found it necessary on medical grounds to retire from the Premiership of Western Australia. His decision has been received with very general regret. Attaining to the position of Prime Minister at an unusually early age he succeeded in winning the respect of all parties by his ability and high sense of duty, and evidences of the regard of his fellow-citizens have been showered upon him. During his recent visit to this country he made many friends, who will unite with us in wishing him a speedy return to health and to active political life.

---

Considering the intricacy of the issues involved, and the long and complicated history attaching to them, The Hague Tribunal has given its decision in the North Atlantic Fisheries dispute with remarkable promptitude. Neither side can claim a complete victory, but, with regard to the more important interests at stake, we believe that the decision will be regarded as generally satisfactory to Great Britain, Canada and Newfoundland. The British Government—which means in practice the Governments of Canada and Newfoundland—establishes its claim to make regulations for the government of the fisheries without the consent of the United States, but such regulations must be *bonâ fide*, and must not violate the privileges enjoyed by the United States in virtue of the Treaty of 1818. Questions as to the reasonableness of specific regulations are to be determined by an expert Commission, on which Dr. Hoek, scientific adviser on fisheries to the Netherlands Government, will have a casting vote. The decision in effect declares that the treaty rights of the United States cannot be whittled away by municipal legislation, but that they do not derogate from the full rights of sovereignty exercised by Great Britain. In the case of bays the three mile limit is to be measured from a straight line drawn from headland to headland, across the body of water at the place where it ceases to have the configuration and characteristics of a bay, special rules for determining the points of measurement being suggested. This part of the Tribunal's award will have an important bearing on other international controversies elsewhere. But it cannot be said that any principle of universal application for determining the limits of territorial waters has yet been laid down, and the fact that Doctor Drago was not in full agreement with his

colleagues upon this question will detract from the importance of the award as a precedent. Refuge must be sought in a famous dictum of Lord Halsbury's, that "a decision is only authority for what it decides." On the questions of customs entry and clearance, payment of light and harbour dues, and the employment of foreigners—which means in practice Newfoundlanders—as members of the crews of fishing vessels, the decision of the Tribunal is, on the whole, favourable to the United States' claims. But in considering the reception with which the award has met, it is interesting to notice that comparatively little attention has been paid to a nice calculation of the comparative gains and losses of each party. The fact that a settlement has been reached is rightly recognized as of more importance than the actual terms of the award. Substantial interests were at stake on both sides, but more important than those interests was the risk of a rupture in international relations arising out of them. This risk is now happily averted, and the cause of international arbitration has received a valuable impetus from the able and dignified manner in which the proceedings at The Hague were conducted. The award has become final and irrevocable, the time allowed for a protest against its terms having been permitted by both sides to elapse.

---

The question as to the three miles zone is one of long standing. International jurists long ago propounded a theory of territorial waters, and obviously some such conception was necessary, but did not agree as to the limit. Gradually the idea worked its way into treaties, not as a recognition of existing rights, but by way of mutual concessions; thus England and France agreed that when at war with another nation they would not carry on hostilities within cannon shot of each other's territory. Various fishery treaties extended the idea, and the three or four mile limit, the conventional distance of a cannon shot, was adopted in the legislation passed to prevent foreign vessels from smuggling. These provisions encouraged the inference that the penal law generally applied within the limit to a foreign ship, but in the "Franconia" case this was held to be wrong, and in the result the Territorial Waters Jurisdiction Act was passed. Over and above this case, there is the conception of an arm of the sea which, though more than six miles broad, lies within the *fauces terræ*. Here the country in question may reasonably assert jurisdiction, and in the Middle Ages the prevalence of piracy made it necessary to recognize this, and to correct the Roman doctrine of "*mare liberum*" with that of "*mare clausum*" in certain circumstances: the Adriatic, Gulf of Genoa, the North Sea and the Baltic have been closed on this principle or its extension. A

remarkable modern case is that of the Bay of Delaware, which, though sixty miles from cape to cape, has been held to be American territory. The general tendency is to take a liberal view of a country's rights in adjoining or partly enclosed waters, and The Hague settlement of the headland question is in harmony with this; but the cases where a rule has been made or proposed that only bays of ten miles width should be considered as reserved for fishing to nationals are mentioned with some indication of approval.

---

The "Further Correspondence relating to the Imperial Conference," published in July, discloses a considerable amount of correspondence on particular subjects, such as the appointment of trade commissioners in the colonies, uniformity in trade marks and patents, trade statistics and company law, the radio-telegraphic convention, and marriage facilities. It sufficiently indicates that there has been a far greater activity, both in carrying out the Resolutions of the last Conference, and in preparing the business for the next, than the critics of the Government and the Colonial Office have been disposed to recognize. The questions dealt with are mostly business matters, but it cannot be said that they are particularly inspiring, or that they demand any special machinery. The big controversial questions, such as preferential trade relations and the development of communications within the Empire, are left as they were. These things lie on the knees of the gods, beyond the industrious activities of the Government department. It remains to be seen whether the Dominions, in response to the invitation sent to them, will provide any more stimulating programme. There is no lack of possibilities. One great ideal, perhaps the greatest, is to preserve and increase the community of ideas and sympathies, which is given us by the common history, language and literature, by settling the social questions which are continually rising up in different shapes on a similar basis throughout the Empire. Some increase of uniformity as to the bases of our social life may appear so valuable as a means of moral and intellectual union that conferences of the future may discuss and formulate schemes, founded on the general experience, for such subjects as alien immigration, women's suffrage and the relations of capital and labour. Views on such subjects undergo constant change and development, and countries which keep more or less in step with one another will have many common causes to help the spirit of harmony and co-operation. There is, as a matter of fact, a keen interest all round in anything that is done in any part of the Empire in such matters, and a considerable exchange of legislative ideas. In illustration of this the following remark,

contained in a minute of the Newfoundland Ministry, may be quoted:—"In connection with the Imperial Secretariat, it has occurred to your Ministers that it would serve a useful purpose, and tend to the unification of the laws throughout the Empire, so far as compatible with the different conditions prevalent in each Dominion, if the new Secretariat were made the means of keeping each Dominion informed of the laws from time to time enacted in every other Dominion as well as in the United Kingdom. This might be done by distributing amongst the various Dominions copies of such laws as are from time to time enacted in the others."<sup>2</sup>

---

Labour questions at home have assumed an unusual and somewhat ominous importance during the latter part of the summer. Trouble between masters and men has broken out, or is threatened, in a number of the most important industries in the country—shipbuilding, mining, the railways, and the cotton trade—while in the discussions at the Trades Union Congress interest has been concentrated on the question of the judgment of the House of Lords in the Osborne case, which threatens to cripple the political activities of Trades Unions. One result has been to draw further attention to the experience of the self-governing Dominions in dealing with similar problems. We have on more than one occasion described the methods of dealing with trade disputes adopted in Australia, New Zealand and Canada, and there has never been a time when they more deserved the careful consideration of politicians at home. The Osborne judgment has drawn attention to the general question of the payment of Members of Parliament, and the different scales and systems of payment in force in the British Empire have been freely discussed in the press of all parties. The wide field of experience supplied by the existence within the Empire of so many self-governing communities living under similar but not identical institutions is of enormous advantage to British statesmen. It is far easier and safer to draw conclusions from the experience of Canada or Australia than from that of Germany or the United States, where the relations of the public to the Government are so unlike those which exist among ourselves.

---

The Report of the Royal Commission on Trade Relations between Canada and the West Indies contains some original features. We believe this is the first occasion on which members of a Dominion Cabinet have been associated in an Imperial enquiry of this kind. It is, also, the first instance in which a Royal Commission has recommended the inauguration of a system of differential tariffs in a group of Crown Colonies. This

recommendation is particularly noteworthy in view of the well-known opinions of two of the Commissioners.

But before any political partisan in this country takes heart of grace from this latter fact, he would do well to study the reasons by which the Commissioners justify their recommendation. The fact is that the West Indian Colonies stand in a very peculiar position. Sugar, which remains their principal product, has always been the plaything of tariff systems. The amount which the British West Indies produce, though considerable in itself, is trifling in comparison with the output of the Continental countries, or of Cuba and Porto Rico. The geographical position of the West Indian Colonies makes them very susceptible to the effects of tariff changes in the United States; and many pilgrimages have been made to Washington on their behalf. The recent policy of the States in relation to their tropical dependencies has rendered these pilgrimages as hopeless as they have in the past proved useless. In these circumstances it is not surprising that most of the West Indian Colonies should have welcomed the hand extended to them by their northern neighbour, Canada.

Canada, in pursuance of her established policy, has for twelve years granted a preferential reduction of duty on British West Indian sugar, without asking or expecting any return in kind. Two or three years ago there was a very general agitation in the West Indies, based on a fear that the preference would be withdrawn, and proposals were made for securing its continuance by the grant of some reciprocal advantages. Whether that fear was well-founded or not we are unable to say; we find no evidence of an intention in this direction on the part of the Dominion Government. But while the discussion was still in progress that Government, moved by the representations of the Canadian refiners, who alleged the existence of a combination amongst the West Indian growers, extended the preferential rate of duty to a limited quantity of foreign sugar. This measure, the growers complained, deprived them of the bulk of the advantage which they had previously enjoyed, and they would be willing to go to some lengths to secure its withdrawal.

The constitution of the Commission made it likely that its work would partake to some extent of the nature of a negotiation between contracting parties, rather than of an enquiry in the ordinary sense. This is exemplified in the part of the Report containing the recommendations as to a reciprocal arrangement. These recommendations are worked out in much detail, even going to the length of submitting a draft agreement for conclusion between the Canadian and West Indian Governments;

but there is little or no explanation or discussion of the terms of this agreement, although they are of some complexity.

The Report lays stress on the desirability of granting preference, if at all, by the reduction of existing duties. As the Commissioners justly observe, a scheme of preference which actually involved an increase in the cost of necessaries would not be favourably received by the general public in the West Indies. Those interested in questions concerning the course of prices under a preferential system will do well to read the evidence of the Canadian refiners, which is summarised in the Report.

---

The Imperial Copyright Conference has resulted in a set of very clear recommendations. The first attempt to form an international union for the protection of authors was made at Berne in 1887, but the convention then arrived at left much to be desired. Not till 1908, however, was the matter taken up again, and the draft convention agreed to at Berlin in that year represents an all-round advance. It is now probable that an Imperial Act will be passed, ratifying the Berlin Convention, and that this Act will apply to the Colonies, subject to the assent of each of the Dominions. The most striking feature of the new scheme is that "formalities" are to be dispensed with; that is, an author need not register his work abroad, though ignorance of a copyright due to an omission to register would bar an action for damages. The continental rule as to the duration of an author's rights is usually for fifty years after death, and, for uniformity, this period is recommended in place of our forty years. The tendency to increase the protection which is given to an author's works is based primarily on a consideration of ordinary justice, but internationally it has been greatly aided by the fact that reprints or translations of foreign works for which nothing is paid to the author compete on very unfair terms with the domestic production, and therefore greatly cripple the development of a national literature. This was notoriously the result in the United States, where for a long period an unexampled sterility reigned. This consideration does not apply to small communities which are not able to evolve any characteristic literature of their own, but now that published prices have been so largely reduced there can hardly be any grievance.

---

Everyone is agreed that one of the first requisites for the closer union of the Empire is a greater exchange of news and current literature, and the extensive reductions which have been made in recent years in the cost of press cables are all to the good for this object. But the matter which is sent out from this country for publication overseas is to a large extent curiously

poor stuff. It might be expected Canada would get good matter, but the Canadian Associated Press, a London agency, has contrived to make some remarkable selections. Last year it cabled part of a trivial and anonymous letter in the London *Mail* regarding Lord Milner and Canada; it sent out a summary of a London *Times* editorial on Canadian Treaty-powers which entirely misconstrued its meaning and caused comments in Canada which were quite unfair, but, under the circumstances, quite excusable; a despatch in October quoted the *Freeman's Journal* as saying something offensive about Canada which later on was found to have come from a letter-writer to that paper in Alberta; on Nov. 30th the following impossible comment was put into the Duke of Connaught's mouth as to the Governor-Generalship of Canada: "I would be tickled to death to get the job!" A new company, however, has now been formed in Montreal and Toronto, with \$100,000 capital, and styled the Imperial Press Service, Ltd., and it is to be hoped that they will give a more plentiful and judicious supply. The tendency of such agencies is to collect paragraphs which appear in the London newspapers about affairs in the possession to which they are sent, rather than to epitomise the affairs of this country. Unfortunately, no newspaper here publishes for export such a summary of facts as that for which the Melbourne *Argus* was distinguished. The Governor of the Colony used to find this summary so convenient that it became an established custom to enclose it in the monthly report to the Secretary of State, in which he discoursed on the affairs of the Colony. In due course the printed summary was found so sufficient that the confidential despatch usually dwindled to nothing, and only the newspaper was enclosed, but the envelope continued to be religiously marked "Confidential."

---

The reports of the Cape Native Affairs Commission throw a good deal of light on the present position of the natives. There are in this province native ministers of religion, newspaper editors, law agents, farmers, shopkeepers, labour agents, teachers, clerks and interpreters in the public service and in lawyers' offices, police-constables, masons, bricklayers, carpenters, cobblers, store-boys and shop assistants, stevedores, checkers, packers, shunters, compositors, postmen, coachmen, grooms, gardeners, farm labourers, domestic servants, labourers on the mines, on railway and road construction, irrigation works, De Beers Explosives Works, and indeed upon every conceivable undertaking in which a demand for unskilled or half-skilled labour makes itself felt. 108,798 labourers left their districts in search of work last year, of whom nearly half were absorbed by the Transvaal mines. The native population of the Colony at

the last census was 1,424,787. The proportion of able-bodied males is about one-seventh, arrived at by dividing the whole population into families of one husband, one wife, one dependent relative and four children; and upon this basis there are 203,541 able-bodied men. Remembering the settled occupations of a large number of the people, and bearing in mind that, even in the reserves, pastoral and agricultural pursuits are the chief means of livelihood, the fact that more than half the able-bodied men leave their homes for work every year is a complete answer to the now happily less frequent charge that the native is not a worker. Indeed, if it were not that the average duration of absence is less than nine months the necessary cultivation of land in the reserves would undoubtedly suffer.

The mere mention of some of the fields of employment in which natives are engaged implies that there has been rapid educational progress in response to the assistance voted by Parliament to native schools. The native press, perhaps the most prominent landmark of educational advance, is not an un-mixed blessing, but it is a valuable channel of information, not only to the native, but also to the student of native affairs, and it affords a free outlet for the discussion of many matters that are the better for ventilation.

The combined influence, in varying shares, of religious teaching, the location school, the example of the trader, the farmer, the Government official, and even of the townsman, produces in the evolution of native character results sometimes satisfactory and sometimes disappointing. Whenever they are disappointing, there is a popular tendency to lament the changed state of the Kaffir, and to ascribe all that is undesirable to the work of the missionary and of the teacher. A fuller appreciation of fact would distribute far more widely both the credit for that which is good and the blame for that which is hurtful in the influences which are brought to bear on an imitative subject race.

These combined influences have worked a great change during the last twenty-five or thirty years in the wants of the native and in his habits of life. The location shop, which formerly contained little more than blankets, heads, hoes, and red ochre, is now in a position to supply ready-made clothing, boots, saddles, ploughs, spades, tea, coffee, sugar, soap, and tinned foodstuffs. Few locations have not at the least a few residents whose household equipment includes a bedstead, table, chairs, cupboard, knives and forks, plates, cups and saucers. There are locations in which the national dress is now never seen, or is seen so seldom as to call forth remark. This change has very greatly added to the consumption by the native of dutiable merchandise, a fact that is often forgotten in computing his

contribution to the public revenue. It is commonly asserted that he contributes nothing but hut tax; as a matter of fact he contributes in direct taxation on exactly the same basis as an European of equally humble means (the average income from all sources of a native in the reserves has been computed at between £25 and £35 per annum), and in addition he is subject to direct taxation, whether in the shape of hut tax or in some other form, which an European would entirely escape.

From every quarter have been received most satisfactory reports of the general state and conduct of the native people. That they are remarkably law-abiding is illustrated by the small number of police required for the administration of justice; in the Transkeian Territories, besides their own headmen there is on an average but one policeman to every four thousand of population. There has been little crime of a serious nature, and the percentage of convictions for drunkenness is extremely low. To their credit also be it said that they invariably respect the persons of European women and children left unprotected in their midst. Generally, the native people are rising in the scale of civilisation; they are advancing intellectually, and by their loyalty, their obedience to the law, their large share in the industrial life of the country, and their direct and indirect contributions to the public revenue, they are responding worthily to the generous policy of this Colony in the administration of native affairs.

---

A remarkable agricultural development has lately taken place in the Cape Karroo, and it is no secret now that this is due to Mr. Abe Bailey. The success has been due to the scientific conservation of water, and already some eighty thousand sheep have been stocked. There can be no doubt that this enterprise is on sound lines. Wool and mutton are and always will be prime necessities, and there are signs that they will increase substantially in value. The consumers are constantly increasing, while the sheepwalks are not. It is not generally realised that, as Australia and Argentina fill up, the lands devoted to wool are gradually being brought under cultivation. If this goes on the next decade may see a great change in the market. It is more difficult to export mutton than wool, but now that lucerne is proving very successful in South Africa, there is no reason why that country should not compete with the other supplies which are eagerly accepted by the European markets.

---

The latest thing in irrigation comes from Canada, in the semi-arid region of Alberta, where the Pacific Railway is carrying out a three million acre scheme on a stretch of country 150 miles

long by 40 wide, comprising 4,000 miles of canals and waterways. This gigantic undertaking, at once providing for population and produce to feed their railways, may be contrasted with the Cape lines running practically empty through a large section of the desert Karroo, which require five acres to feed one sheep, half of which are swept off by every recurring drought. The distinguished engineer who is now engaged in a great scheme for revitalising the Mesopotamian Desert propounded a scheme for canalising the Orange River, whereby some of these non-producing regions would have been rendered equally productive with that of the American deserts, but it never got beyond the paper stage, whereas Victoria, about one-third of the size of the Cape Colony, has spent £12,000,000 in reclaiming her waste lands, and at the present moment is advertising for 40,000 families for settlement purposes. The improvement of the Cape in this matter is, it may be hoped, only a question of time, and will be of enormous social as well as economical importance, as it will afford employment on a great scale to the white race. It is not pleasant to hear that in some districts the natives have clubbed together to buy out the whites, and are increasing at a rate that threatens the crowding out of the latter. The improvement of the agricultural conditions is the only means that can turn the tide.

---

The Hong Kong Government has published an extremely interesting account of the history and prospects of Hong Kong University, written by Sir Frederic Lugard, whose enthusiasm and perseverance have done so much to convert the scheme into a reality. In some "Notes for readers in England," appended to the memorandum, it is pointed out that the scheme has important bearings on the general question of the position of British interests in the Far East:—"Already in the Far East, France and especially Germany are taking steps to promote the study of their own languages, and to supply the demand for Western Education. If British interests, both commercial and political, are to be maintained in the face of the friendly rivalry of other nations it is essential that the predominance of the English language should be unchallenged, and that it should be the medium of acquiring Western knowledge. Simultaneously with the new demand in China, the political aspect of affairs in the Far East has undergone a radical change. With the acquisition by Japan of Western civilization and learning, and the advent of European and American competition, Great Britain no longer holds the unique position she did in old days, and new efforts are needed. The establishment of a University in which English is the medium of instruction cannot but give a great impetus in this direction, and as the Director of the Khartoum College remarks

of that institution, 'It is unthinkable that a life of the kind which the students lead for five years can fail to produce a profound effect on their character and general point of view.'" Hong Kong has recognized that in this matter a special duty devolves upon the Colony. "The large majority of its population are Chinese, and, with the exception of Macao, it is the oldest Western settlement in China. Its geographical position—in close proximity to the great centre of population at Canton—and its predominance as a port and mart of exchange, all combine to indicate that it is the natural centre for Western education in the East. The advantage taken of our existing educational agencies by the Chinese from the mainland—the confidence they have inspired, and the success they have achieved—together with the traditional friendly relations between the Colony and China, combine to offer every prospect of success."

---

The realisation of the scheme was in the first instance rendered possible by the munificence of Mr. (now Sir) H. N. Mody, a Parsi gentleman 50 years resident in Hong Kong, who offered to erect the necessary buildings, at a cost of \$150,000, and to provide \$30,000 towards an endowment fund. When it subsequently appeared that the proposed buildings could not be erected for \$150,000, Mr. Mody agreed to bear the cost of their erection, whatever it might be, but intimated that if the cost exceeded \$180,000 he could not be responsible for any contribution towards the endowment fund. The appeal for subscriptions met with generous support. Messrs. Butterfield and Swire and allied firms, on the initiative of Mr. J. H. Scott, contributed no less than £40,000; the Viceroy of Canton gave \$200,000; and His Majesty's Government promised to provide £300 per annum for scholarships, to be held by British subjects, the holders being entitled "King Edward VII. Scholars." The Hong Kong Government undertook to provide a site free of cost, and the Hong Kong College of Medicine, which was on the point of initiating a new scheme for its expansion, agreed to incorporation in the new University.

---

Thanks to the remarkable energy shown in so many quarters, it was found possible to lay the foundation stone of the new buildings on March 16th last, and it is hoped that the University may be opened early in 1912. Sir Frederic Lugard offers some interesting remarks on the curriculum of the new University:—"There is a class of critics who hold the view that higher education conferred upon Orientals, especially in speculative and theoretical subjects, tends to produce a discontented and even a revolutionary class of men for whom there are no adequate

openings and careers in life, and that the neglect of a more practical education is responsible for the 'unrest' in India. As applied to the British Empire, I myself strongly hold this view. The two first Chairs established in our University, viz., Medicine and Applied Science (or Engineering) are therefore eminently practical ones, and the demand for qualified men in these subjects is limitless. We have added a third faculty—that of Arts—to enable undergraduates to qualify for official appointments, and this degree in the case of Chinese will include the Chinese language, history and literature, which it is above all important for them to know, and should be the basis of their education, so that it may not be said of Hong Kong graduates, as was said by Mr. Fraser of Indian students, that 90 per cent. of those who take English degrees cannot write the language of their parents. In whatever branch a student graduates it is our aim to turn out practical men well qualified for the careers which they intend to adopt."

---

No matter is more important in the long run to the Crown Colonies than the education of the native, but it cannot be said that the subject has been thought out in a thorough and systematic manner. Government authorities are apt to restrict their energies to questions which call for prompt settlement, and the whole machinery of offices is adapted for the daily disposal of current points rather than for constructive work for which time and the consideration of general principles are required. Exceptional interest therefore attaches to a memorandum by the Governor of Ceylon, published in the Colony, which discusses the suitability of the ordinary English literary course for Ceylonese, and the claims of education of a more practical and elastic character. Sir Henry McCallum contends strongly for the utilisation of vernacular languages and manual instruction. At present the colonial system follows the home system, and if, as many critics say, the latter is wasteful of time and energy, it must be much more so when transplanted to another country where the language and associations are different. Sir Henry McCallum is, we gather, of opinion that even at home the classical education of the old sort is doomed. "The dead languages are slowly but surely being ousted from the fetish groves where for so long they have been superstitiously worshipped. Already is to be heard the swan song of Greek." We do not know whether the horrid shades of the fetish groves would accept this pronouncement. As a matter of fact, the amount of Greek required there is not less than it used to be; it is distinctly more; nor is there any particular reason for its elimination

so long as the great majority of students find in classics the most convenient training for their intended professions—the Church, the Bar, the Civil Service, public or literary life. The subject is simplified by allowing Oxford and Cambridge to go their own ways; at any rate they have a high ideal, and there are other universities for other purposes. But where the student starts with a mother-tongue which is not English the difficulties of such a course are, except in special cases, prohibitive. “The great majority of our youth start their school days by working in English as a foreign tongue. Slowly they learn to speak it, and ultimately perhaps even to think in it. But meantime much of this work has been quite unintelligent and purely by memory. The departmental reports prove that much of the teaching in our schools is painfully stupid. The reason is largely that the masters have been educated through the medium of at best a half-known tongue, and are now using it in order to teach others. But in spite of this, our better boys learn English well enough to speak it fluently, and to pass the Cambridge Senior. They then are beginning to feel free to study in the tongue they have acquired, and commence to consider their choice of a university. At once the Department steps in and recommends of all B.A. degrees that of London. In other words, the unfortunate lads are to read for their Intermediate in Latin, French, Greek or German, and Mathematics. No sooner have they got beyond the memory and rote stage in English, no sooner is the path opening out before them to an appreciation of literature, a study of the sciences and philosophies, than the vision is shut out and they are thrust back to another deadly struggle with grammar, prose, and idiom. English boys study the classics primarily for the sake of culture and for the advantage which facility in the idioms of and translation from a foreign tongue gives them in the use of their own. But they have from their earliest years been familiarised with much of the history and culture of Rome, by allusion, interesting books of adventure, and countless illustrations. They have a background into which to fit all they learn at once, and Julius Cæsar, Brutus, and Hannibal, and the great Cunctator, are as near to them as Marlborough, Watt Tyler, or Oliver Cromwell. In Ceylon it cannot be so: the background neither is, nor should be, there. If it were, it would not be culture, but a slavish imitation of an alien culture—a very different thing. So then Latin and Greek cannot here play the important part in culture-training which they occupy in England, nor can they with any seriousness be advocated as a means of teaching fluent English. On the contrary, English may do here almost all Latin and Greek do in England. The rest can be supplied from the classics of the East.”

The crux of the matter lies in the last remark. The classics of the East is a broad expression. They are for practical purposes contained in languages which are not vernacular in Ceylon. Cinhalese itself does not provide the materials for literary culture. It should undoubtedly be taught elementarily, but the higher education should on every ground be carried on in English. This is generally true of the Colonies, outside India. But the type of English education should, as contended by Sir Henry McCallum, be moulded to suit local character and surroundings. The difficulty is that any variations from the English curriculum would stand in the way of preparation for the Cambridge Local Examinations and the London courses. This might be met by special examinations and diplomas. In any case, some manual training could be given, as is now done at most public schools in this country. In this connection, attention may be called to the fact that the London B.Sc. can be obtained in Agriculture and in Veterinary Science, and it would be a good thing if some colonial students took up these courses. At present nearly all the Ceylon Government scholars are reading for the Civil Service Examination—hardly a desirable result, and in marked contrast with the Straits and Mauritius scholars, who hardly ever think of this lamentable resource.

---

The formation of a great number of rubber-growing companies has brought considerable new capital into the Malay States, but the majority of them took over old estates and the vendors of the planter-proprietor class have only in a few instances started new estates. A vast amount of country awaits development. No one can say that the expenditure to encourage progress has been of the penurious order. New roads and the repair of existing roads account for about \$4,000,000 a year, and this year over \$5,000,000 will be devoted to the West Coast Line and \$4,000,000 to new constructions. Roughly, nearly two-thirds of the annual revenue is being expended for the purpose of facilitating transport and preparing the way for people who wish to exploit the undoubted agricultural or mining resources. Hitherto this large expenditure has been rendered possible by a heavy tax on the tin mining industry, by the recognition of public gambling houses, and by the opium revenue. It is to be feared (from the strictly financial point of view) that the establishment of a higher moral standard in the latter matter will cut off a good deal of revenue. The export of tin was less in 1908 than in 1904, and only in Perak, the one State where there are many European mining companies working on more or less scientific lines, is there any indication of a material increase in

the output, and competition from Bolivia and elsewhere may prove severe. The large sums which have been spent on eastern development, and the £4,000,000 to be lent to Siam for railway construction, fall on the Western States, and at present it cannot be said that much tangible result has followed. It cannot be expected that the East Coast will be taken in hand by cultivators until the West Coast is filled up, and this is far from being the case. But considering the opportunities and sacrifices which have been made to encourage industry, the time has come to make an effort to advertise Malaya in this country and to attract capital. Steps are being taken with this object, and the organisation of the business is in good hands, as it is being attended to by Sir William Taylor, K.C.M.G.

---

The action of the Union Castle Company in deciding to establish a service via the Suez Canal to East Africa is highly welcome. Even with a minimum of sentiment in such matters, it can hardly be considered satisfactory that British Governors and officials and troops should have to journey to our possessions by foreign ships, and the absence of a British first-class through service, for passengers and freight, means that much trade which might come to this country is taken elsewhere. The case has long been recognised as one which would justify, if ever a case does, exceptional treatment. More than one suggestion was put forward, but for a long time it appeared that it would be impossible to secure a British service of a satisfactory character without a heavy subsidy. The object has now been attained without a subsidy. The Government undertakes to give the service as much support as it can, under reasonable conditions, in respect of its own shipments and official passengers. This is substantially what would happen in the ordinary course without any agreement at all. Government officials will be required to sail by the Union Castle Line, but it is a good bargain for them to secure such a service. No monopoly, however, is given to the line, as in the event of any other company putting on a service of similar quality it is, under the agreement, open to the Government to avail itself of the lowest rates. From all points of view the negotiations conducted by Colonel Seely have had an exceedingly satisfactory result, which no one would have anticipated a year ago.

---

The *Statist*, in an examination of the possibilities of East Africa, urges the further construction of railways, and pronounces strongly on general grounds in favour of Government ownership.

“It seems to us plain that the wisest policy is construction by the Government. In new countries like British East Africa and Uganda it is certain that a railway company will not be able to

raise capital sufficient for the purpose of opening up these territories except, in one form or another, it gets assistance from the Government. This is proved conclusively by experience in both as well as in the United States and Canada. But why should the British Government, whose credit stands so high, sacrifice a future asset of great value to the future inhabitants of the country by calling in a company or companies to its assistance? If it gives simply a guarantee to a company, the company really is working with a capital which is the produce of the credit of the British Government. It is, therefore, if the enterprise turns out well, receiving reward for a capital it did not itself provide. If, on the other hand, the assistance is given in the shape of large land grants a very considerable part of the soil of the country is alienated, and goes to swell the profits of an unnecessary assistant. In the United States at the present day it is recognised that the resources of the country have been wasted in the past, amongst other ways, by the manner in which assistance was given to limited liability companies engaged in railway construction. Our Government should realise all this, and in opening up British East Africa and Uganda should take great care that it does not in any way waste the resources of those territories. It has the experience of other countries to guide it, and it ought to be warned by that experience.

“ But it is objected that companies work more efficiently and cheaply than a Government. We are by no means sure that that is so. The Post Office and the Admiralty are generally believed to be efficient and economic; while it would be easy to point out companies which are neither. As a matter of fact, there is no reason why a Government should not be as efficient in every sense as a company. Whatever care might be taken in forming railway companies for the two territories we are treating of, it may be taken for granted that the directors would have little personal knowledge either of British East Africa or of Uganda. One or two might have spent a time in either; but the strong probability is that the directors would be chosen for reasons in no way affected by their ignorance of the countries in which the companies are to work. Moreover, if such companies were formed the directors would, we may take it for granted, reside in London and would manage their business from London. They would have to choose here in London those who were to lay out and construct the several lines, and they would be very much at the mercy of the persons chosen for these purposes.

“ It is obvious that if land grants of magnitude are given to railways the whole land policy of the future communities is pre-judged. They will have no means of altering it. On the other hand, if no such grants are made, it will be at the option of the

people to decide what is to be their land system. Again, if such land grants are made, and the railway or railways construct towns on those grants, the building sites will belong to individuals, and the future policy of the community will again be prejudged. On the other hand, if the Government retains the whole land in its own possession, it will be at the option of the future inhabitants to adopt a policy of unearned increment without violating any established right or doing injustice of any kind to any individual."

The weight of these arguments is undeniable. An exception may be recognised in favour of railways which are required in connection with some private enterprise, such as a line to give access to a mine. Here the finances of the railway are merged in those of the business, and an undertaking which would be unremunerative in itself may be thoroughly justified by the economies which it effects in the management of the affair. There are also speculative cases where capitalists are ready to take a risk which a Government could not properly do. These, however, are very few. The chance of success in the Colonies, assuming equal management, are clearly greater when the Government is the owner than when the line is private property.

---

The year 1909-10 was the most successful agriculturally that Nyasaland has yet experienced and large areas of land have been taken up. Cotton appears to be the most suitable product and is rapidly increasing, thanks largely to the judicious expenditure of the Government funds granted. The Director of Agriculture, Mr. J. S. J. McCall, states that since the introduction of native cotton cultivation in Nyasaland by Government it has steadily progressed, and the crop for the year under review amounted to 220 tons, an increase of 130 tons on the previous year. The crop now approaching maturity is favourable, and as the distribution of seed is practically double that of last year it is anticipated there will be as large an additional increase as in the past season. The quality of the native grown Nyasaland Upland has always been as good if not better than European grown, but the Egyptian crop was very disappointing in the past, being largely composed of mixed staple. Last season a marked improvement has been brought about by teaching the natives how to grade, and a large quantity of the Port Herald native crop obtained 1s. 1d. per lb., one of the highest prices obtained for Egyptian grown in the Protectorate. One of the great drawbacks to the native cotton industry is the distance between some of the cotton fields and the ginneries, but the British Cotton Growing Association are establishing a ginnery at Port Herald in the largest native cotton centre of the Protectorate, and they

may be encouraged to erect another near Lake Nyasa to gin the cotton produced on the Lake.

---

The future of a large part of Africa depends on the question whether the resources of civilisation can fight the ticks. Until this is done, immense tracts will remain practically uninhabited and many territories will be terribly crippled. There are two effective ways of fighting the evil, but the difficulty is to apply them. The first is the dipping of the "hosts." The best dips contain arsenic, and if applied to the animals every five days or so are found to destroy all species of ticks; in some cases an interval of fourteen days can be allowed. This method is practicable where there is little game and the cattle can easily be collected. The other remedy is to clear a space of animals so that all ticks in it must die through the absence of hosts. A period of nearly two years is required for the process. Burning the grass helps the destruction and the driving out of game, but, of course, it would be impossible to exclude all game from any large area, and total eradication is therefore under present conditions beyond attainment by this method. The dipping process is effective on farms, and as its use expands the trouble will diminish. The wild animals will still be left, and in the future no doubt they will be cleared from areas which will then become fit for occupation by cattle. This means eventually the same extermination of wild beasts in Africa as has taken place in long settled countries, though for a different reason; they are terrible now, not from their own strength, but as carriers of deadly insects, and in the interests of domestic animals must be destroyed, just as mosquitoes are in the interests of mankind. The process will be nothing new in Africa, as the practice is growing of running sheep and ostriches in netted camps, partly to keep off the carnivora and partly to save labour. It may be found that certain animals are more liable to act as carriers than others, and it is by no means always the case that big game are the chief offenders, as in some districts when they are absent the tsetse flourishes.

---

There are still many pagan tribes in Northern Nigeria who remain blissfully unconscious that the commissioners and missionaries are on their track, and that the days of head-hunting and other like recreations are numbered. The native in such parts has not entered into the seriousness of life and amuses himself sufficiently with the primitive sport of fighting, usually without carrying the fun to excess. Capt. A. J. N. Tremearne gives a typical case in a paper which has appeared in the *Journal* of the

Royal Society of Arts. "Some of these peoples are a wonderfully sporting lot: if they cannot win they give in smilingly. A couple of years ago Fada Wate (Ninzam tribe) had been inciting other towns to resist us, and, on being summoned to surrender, sent the reply that they would like a little fight first, and, if they found that they were not strong enough, they would give in. Of course, the rifles were too much for the arrows, and after about half-an-hour the people had had enough. The Resident, entering into the spirit of the joke, chaffed them about their resistance, and they informed him that they wished to see if we really were stronger, because if we were, they could depend on our protection against their neighbours later. All were apparently quite pleased with the experiment! Life is of little account, bows and arrows are always handy, and if a town is not fighting another it will divide against itself. Even the women in Ninzam love a fight, and they once turned out against me for arresting their chief—hanged later for several cases of murder. Fighting seems to be *the* amusement. The great cause of this is guinea-corn beer. It enters into all their religious rites (with some tribes ghosts were laid with it), and by its amount is measured a man's popularity. Consequently all the foodstuff is drunk, and from about June to November (when the new harvest comes) the people are in a state of destitution and loot each other's stores for food, and even steal the children for sale as slaves."

Perhaps the practice of using up the food to make intoxicating drink is carrying the game too far even for a sportive race, and justifies the policy of peaceful expeditions which carry the olive branch but are nevertheless ready to enter into the spirit of the thing by an occasional brush.

---

It is rather curious that the first occasion for many years on which a contract has been given out for the construction of a Crown Colony railway should have been followed by a law suit. In the action of Mr. C. F. Bamford against Mr. W. W. Murphy (the Accra Railway case) the short facts were that the plaintiff, who had been engaged on railway work in Lagos, brought the Accra matter to the notice of Mr. Murphy and prepared materials for a tender; the tender put in by Mr. Murphy was accepted, but Mr. Murphy did not employ Mr. Bamford to carry out the work. The latter, in the action, contended that there was a partnership, and successfully in the Lower Court, but the Court of Appeal held strongly that there was no evidence of this. Mr. Bamford, as we understand, received payment for his services, but his claim went much beyond this, being in fact for half-profits. The moral is the fairly obvious one that a man who

relies on what he regards as an agreement should have written evidence of it. Verbal arrangements are difficult to prove and often appear in different lights to the respective parties. Elementary as this proposition is, it is notorious that unwritten or slipshod agreements are by no means infrequent in engineering matters.

## UNCONSTITUTIONAL GOVERNMENT ACTS.

Wherever there are two legislative chambers there is the possibility of conflict, and colonial history is rich in examples of such entanglements. The embarrassment caused by a block of the legislative process is naturally most acute when it is the authority for taxation that is stopped. There is a general understanding that the Upper Chamber is within its rights in rejecting a measure dealing with policy or principle, but that it should not attempt to amend any Bill providing for revenue. But on many occasions it is impossible to keep the two things apart. Great administrative changes may be quietly embodied in a formal appropriation. If in such a case the Upper House fails to pass the Bill, the double result follows that the change is not carried out and the monetary necessities of the administration are not provided for. The Government, it is clear, cannot enforce the collection of the taxes in question after such a rejection. Taxes, it is true, are levied in this country on a vote of the House of Commons before they are imposed by law. The justification for this is solely the presumption that the Bill to be founded on the resolution will become law. If this presumption is defeated by the action of the Upper House, the taxes cannot be legally collected and no Government would attempt to impose them. The only courses open to the Government are to resign, which may be futile if the other party has no chance at the polls, or to borrow money and to use it for the usual purposes. In this country, on the recent occasion, the latter course was taken by the issue of Treasury Bills under express statutory authority. But in a colonial case, where the Governor, on the advice of his Ministers, did exactly the same thing, though not under the same statutory authority, he was condemned in the most emphatic manner by the Imperial authorities. And a matter

of such constitutional importance justifies a retrospect of the circumstances. The parallelism of the occasion is the greater in that it arose out of a Free Trade and Protection controversy, but there the similarity ends, as it was the Government that was the author of a "tariff reform" measure and the Upper House was upholding free trade.

A general election took place in Victoria in 1864. The opinion of the constituencies was considered by the Ministry to be expressed strongly in favour of revising the Tariff of Customs Duties upon the principle of reducing the import duties on tea and sugars and the export duty on gold, and substituting for these reductions other duties, principally upon made-up goods of all descriptions, popularly called soft goods, but admitting the manufactured material, cloth, cotton, linen, leather, etc., duty free. The object of this was stated to be to encourage "native industry," or in other words to induce the employment in trades of the youth of the country. Soon after the tariff was introduced into the Assembly, where it was supported by a large majority, although much opposed by the merchants out of doors, it became evident that it was very likely to be rejected in the Legislative Council. In hopes of preventing this, the Assembly, on the proposal of the Ministry, who were in fact the expositors of the views of the majority, determined to unite the tariff with the usual Appropriation Bill, and it therefore did not go up to the Council until the close of the session was supposed to be approaching. This proceeding was justified in the Assembly by the case of the repeal of "the Paper Duties Bill" in 1861 and the course pursued by Mr. Gladstone and the British Ministry on that occasion. The Council determined to resist this pressure, but instead of rejecting the Bill sent up from the Assembly, passed a resolution laying it "aside," but declaring that they were ready to consider both the measures, viz., the usual Appropriation Bill and the tariff, when sent up as separate measures. The Council did not, therefore, on this occasion finally reject the tariff. The Assembly then passed a resolution, declaring that they would send up no other Appropriation Bill until the Council recognised their claim to regulate the taxation of the Colony by passing the tariff. These proceedings took place in July. The resolutions on which the new tariff is founded had been adopted in February; and, pursuant to the usual practice at home and in many Colonies, in conformity, too, with three distinct precedents within the last eight years in Victoria (the most recent being in 1862, when new and higher duties were thus collected for five months), the new scale of duties was put into operation, subject to the duties being returned in the event of the tariff not becoming law.

Communications were then interchanged between the two Houses without any good result, until in November the Council declared that they intended the "laying aside" of the Bill as a final disposal of it. The Assembly immediately sent up the tariff in a separate Bill and the Council rejected it. The duties ceased to be collected the next day, and were ordered to be refunded in most cases.

The only cases in which the refund was delayed were those in which an appeal was made to law. When the Council laid aside the Bill in July, certain merchants were advised to bring actions for the recovery of the duties they had already paid in deposit. A judgment which, *as to the facts*, affirmed that the duties were not leviable under the sanction of law, was given by the Supreme Court. It involved points of law, and these were not decided on by the Court and final judgment entered up until December, a month after the duties had altogether ceased to be collected.

Up to the time that the Council laid aside the Tariff-cum-Appropriation Bill, the public expenditure had been provided for by Acts concurred in by the three branches of the Legislature, passed from time to time, and sanctioning the issue from the consolidated revenue of the necessary sums; the expenditure, that is to say, the several *services, recipients, and amounts*, being fixed by the *estimates* which had passed the Assembly in the early part of the year.

The Appropriation Bill, which was conjoined with the tariff, and included the amount required for the public service for the rest of the year, having been only laid aside, and the Assembly not recognising this proceeding as a rejection, that body would not send up another Bill.

In the absence of the Appropriation or another Bill sanctioning the application of money, the Auditors would not certify that money was "legally available" for the public service, and it therefore could not be drawn from the banks, where, according to law, it was deposited as collected.

With the exception of the Governor's and Judges' salaries, and a few other items, the whole service of Government, including police, gaols, troops, asylums, contracts for provisions, and of every other description, which had been entered into *as usual* at the beginning of the year, upon the faith of the Estimates, was thus left unprovided for, to the annual amount of little under two millions, which had been regularly distributed at the beginning of every month, in a country where advances could only be obtained at an enormous charge, by way of premium.

For one month these payments were stopped. The Governor tried in vain by message to reconcile the Houses. The prospect

of being unable to pay for a second month approached. The Assembly addressed the Governor, requesting him to take measures for maintaining the public credit and the efficiency of the Civil Service, and assured him they would support the Government, affirming that the Council had laid aside the Bill without message or communication to them.

After considering and discussing more than one expedient which was rendered impossible by the refusal of most of the banks, who were under the influence of the leading merchants and Legislative Councillors opposed to the tariff, to co-operate, one bank agreed to make such advances as the Government required, upon condition that they should be promptly repaid.

This repayment was effected under a local law for facilitating the recovery of debts against the Crown, by the Attorney-General confessing judgment for the amount of the successive loans. Upon the certificate of the proper officer of the Court being presented, the Auditors certified that money was "*legally available*" for payment of the amount. The payments were strictly limited to *liabilities* of the Government, and did not include any new grants provided for by the Appropriation Bill.

Immediately after this plan was adopted the Assembly passed another Address, which the whole House presented to the Governor, thanking him for the steps he had taken and approving of the scheme.

The Council had twice publicly, by resolution and address, declared their readiness to pass the Appropriation Bill as it had come from the Assembly; and the Crown Law Officers advised the Governor in writing that it was within the legal competency of Government to contract for the loan of money to meet the liabilities of Government, in the same way that it had always been considered competent to them to make contracts for supplies or other purposes of Government upon the strength of the *Estimates alone*, which passed the Assembly at an early period of the session, while the Appropriation Bill rarely becomes *law* until nearly the close of the year. Such contracts had, in fact, been recognised by the Supreme Court.

The view, which from various causes the Governor was led to take of the opinions held by the constituencies, convinced him that the difficulty would not be solved by a dismissal of the Ministry and an appeal to the country. But when the Council finally rejected the tariff, and the Assembly, adhering to their resolution, would not, as the Governor was informed, send up another Appropriation Bill, a dissolution was resolved on, and the result was that the new Assembly contained a majority of fifty-eight in support of the Ministry and their past policy and proceedings, in a House consisting of seventy-eight members.

No doubt money had been issued to pay the public debts without the sanction of the Legislative Council, formally given by passing the Appropriation Act. This step, taken with the concurrence of the Ministry and the Assembly, was the head and front of the Governor's offending.

The Secretary of State (Mr. Cardwell) lost no time in condemning the action taken by the Governor (Sir C. Darling). He condemned both the levying of the taxes and the borrowing of money. The following extract gives the substance of his views:—

“First, I have no hesitation in saying that independently of the Judgment of the Supreme Court, no consideration, at least none that is discernible in your despatches, should have induced you to give your concurrence to the levying of these duties.

“The plea that taxes are levied in this country on a vote of the House of Commons before they are imposed by law is manifestly irrelevant. Such taxes are so levied because it is not doubted that the Bill imposing them as from the date of the resolution of the House of Commons on which the Bill is founded (and after which only they are levied) will become law, by the concurrence of the two other branches of the Legislature. If such concurrence were withheld, the sums so levied by anticipation would be repaid, and they would of course be no longer levied.

“But in the present case you and your Government were perfectly aware that the Bill would not receive the sanction of the whole Legislature, and the exaction of these duties was not in anticipation, but in defiance of the judgment of the Legislative Council. It was, therefore, not only in its origin unlawful, but there even was every reason to presume that it would remain so. I look with extreme apprehension on a state of things in which the Government of a British Colony is engaged in collecting money by mere force from persons from whom the Supreme Court has declared that it is not due. It is an example of violence which may do incalculable mischief beyond the limits of the Colony in which it has been allowed to occur.

“Next, I do not understand on what ground it can have been imagined that you were legally authorised to borrow from a private bank large sums of money on behalf of the public. No authority is alleged, and I am unable to conjecture any. The only excuse for such a proceeding would have been an overwhelming public emergency of such a nature as to justify what was not justified by the letter of the law. But, as I have observed, you had already declared that no such emergency existed. And you were right; no such emergency did exist. If payments were legally due from the Crown to public officers for salaries, or to any other persons on any account, it was open to such persons to recover what was so due to them in the ordinary course of law.

It was for one or other branch of the Legislature to yield, or for both to compromise their difference. It was not for you to give a victory to one or the other party by a proceeding unwarranted either by your Commission or by the laws of the Colony. I must point out that by such a proceeding the Governor and his Government, with the co-operation of a local bank, might at any moment withdraw any amount of public funds from the "Public Account" to which it is consigned by law, and place it at their own command, relieved from all the checks with which the Legislature has carefully surrounded it.

"Thirdly, as to the expenditure of the moneys thus obtained, I find it difficult to suppose that by the Crown Remedies and Liabilities Act the Legislature intended to enable the Government to discharge, without its concurrence, those ordinary expenses of Government which it reserves to itself the right to re-consider annually. It may, perhaps, be doubted whether office-holders who are under a standing notice that their salaries are dependent on laws, annually passed by the Colonial Parliament, would be treated by the Supreme Court as having a claim upon the Government independently of any such law. But it is not alleged that the Supreme Court was ever called upon to give judgment on the question, and you do not inform me of any law which would warrant you in paying away any public money except under the authority either of such a judgment or of the Auditors' certificate.

"As at present advised, therefore, I am of opinion that in these three respects—in collecting duties without sanction of law; in contracting a loan without sanction of law; and in paying salaries without sanction of law—you have departed from the principle of conduct announced by yourself and approved by me—the principle of rigid adherence to the law. I deeply regret this. The Queen's Representative is justified in deferring very largely to his Constitutional advisers in matters of policy and even of equity. But he is imperatively bound to withhold the Queen's authority from all or any of those manifestly unlawful proceedings by which one political party, or one member of the body politic, is occasionally tempted to endeavour to establish its preponderance over another. I am quite sure that all honest and intelligent colonists will concur with me in thinking that the powers of the Crown ought never to be used to authorise or facilitate any act which is required for an immediate political purpose, but is forbidden by law."

In considering this pronouncement it is necessary to bear in mind that the duties were only levied during the period while the Bill was "laid aside" by the Council. They were discontinued when it was rejected. It was common ground that during the interval the collection was not authorised by law,

but it was defended by the Law Officers of the Colony on the ground of constitutional practice.

“The practice is not, indeed, authorized by an express law, either in England or in Victoria, but it is a convenient, and in some cases a necessary means of preventing unhealthy speculation and disturbance of prices, and it is justified by the presumption that as the Legislative body, which has the sole right to grant aids and supplies to the Crown, has sanctioned by resolution the imposition of the duties, the other branch of the Legislature will not interfere to prevent the resolution being clothed with the form of law.

“The lapse of seven months from the date of the resolutions does not appear to be a circumstance that affects in any degree the legal aspect of the question. The collection of the duties was equally unwarranted by law on the first day they were so collected as at the present time: it is warranted in a like degree by necessity, by usage, and by the authority of the Legislative body, that has the control of taxation at this day, as at the time when the duties were first enforced.

“The Supply and Appropriation Bill has not been lost. It has only been laid ‘aside’ by the Legislative Council; and although it is not very clear what is the precise effect, according to Parliamentary practice of the ‘laying aside’ of a Bill, it is believed that there is no express rule of Parliament that would prevent the Legislative Council resuming the consideration of a measure ordered to be laid aside; even if the Bill in question had been lost, however, that circumstance would only impose on the Government the necessity of bringing in a new Bill, as was done by the Government in England in the case of the Malt Duty Bill in 1807, and would not destroy the presumption above mentioned upon which the Government deemed that it was justified in commencing to collect the duties.”

Thus the collection of the duties was not, as the Secretary of State put it, “in defiance of the judgment of the Legislative Council.” No “judgment” had been given. Apparently, however, Mr. Cardwell’s view was that the action of the Council in “laying aside” the Bill should have rebutted the ordinary presumption that the supplies would be sanctioned by that House. The logical result of this principle would be that the levying of duties in such cases is indefensible if there is any reason to apprehend that the Upper House will reject the Bill, and it is unreasonable to expect that any Government will suspend the action which it thinks necessary in deference to a future decision which may or not be carried out.

With regard to the borrowing, the argument that persons to whom the Crown owed money had a remedy at law was singularly poor. The success of multitudinous actions against the Government in the Courts cannot, from any point of view, compensate for national bankruptcy. Mr. Cardwell stated that no emergency existed. News at that time was not transmitted as it is now, but one of the despatches acknowledged stated that "I believe that the emergency (upon the critical nature of which, in a community wherein it has been for years the custom to make all the disbursements of Government, amounting to a considerable sum, every month, it must be unnecessary to comment) was such as to render it my duty to avail myself of any law rather than run the risk of being obliged, however reluctantly, to act in direct contravention of more laws than one; or to allow a state of confusion to arise which might eventually have necessitated, in parts of the Colony, the suspension of all law except that of a military nature." It is obvious that it could not have been otherwise.

The controversy ended in the dismissal of Sir C. Darling. It illustrates the fact that, while it is generally admitted that necessity knows no law, the people who are on the spot are more likely to feel the necessity than people who are not. The despatches of the Secretary of State were written from a high platform and with some superiority over the facts. His own Government had not been in the same case. It is agreed that under such circumstances the levying of taxes is illegal and that the borrowing of money is unauthorised, but when the regulation machinery breaks down the work of administration must be carried on by other methods. The working of the British form of Constitution entails the existence of certain conventions, and in some extreme cases Ministers have to act without any statutory power, and to put themselves right in point of form afterwards.

In a recent Transvaal case, which was discussed in the House of Commons in July, the Government advised the Deputy Governor to sign a warrant for certain payments which had not been authorised by law, but which he had power as Governor in Council to provide for if they appeared to him, as such, necessary in the public interest. It would seem, therefore, that the warrants so issued were legal if this condition was fulfilled, and as to this he was bound to act on the advice of his Ministers. Whatever fault there is in the case lies in the legislation, and undoubtedly such provisions furnish a procedure which tends to do away with the control of the Upper House in financial matters. The difficulty is that it is desirable that there should be a statutory means of making payments in times of emergency or necessity, but under self-governing Constitutions it must be for Ministers to

decide whether any such state of things exists. The Legislature must be the eventual judge of the merits of the matter. The discussions of this incident have turned a good deal on the judgment in an action brought by the dissenting members of the Executive Council. In this case it was held that the payments were illegal, but this was before the warrants were signed, and at that stage the payments were clearly unauthorised in any way; the technical position was altered by the issue of the warrants, and the Court held clearly that the real remedy of the complainants was to go to Parliament.

The question has occasionally been discussed as to how far a Governor is liable to be sued for acts done by him in that capacity. At one time it was believed that he could not be sued in Colonial Courts, but the decision in the case of *Musgrave v. Pulido* by the Judicial Committee rudely disturbed this view. It led to the raising of the point whether greater protection should be given to Governors against suits in Colonial Courts, but nothing came of this. To justify an illegal act a Governor must rely on a subsequent validating or indemnity statute. This would cover such cases as the above, but in those where a criminal action would lie in this country it would seem that, as in the *Eyre* case, a Colonial Act of Indemnity is only efficacious if the proceedings in question are held to have been necessary.

## SOME FIJIAN CRICKET.

The appearance in *The Sketch* of the 20th July last of a group of Fijian cricketers, makes me think of how the game is sometimes played in the remoter villages of our dear Cannibal Isles. These remarks do not apply to the team portrayed in the picture, whose members live in the immediate vicinity of Suva, the capital of the group, and who, trained under strict European supervision under the leadership of Mr. Marsden, in 1907 played a series of matches in Sydney, Melbourne, Brisbane, Adelaide, and in many other of the principal Australian towns. Its career was not inglorious, though scarcely in the first flights of the great Southern Continent. But now they consider themselves past-masters of the sport, and discuss and criticise our leading players, though to the uninitiated it would be difficult to understand what they were talking about, the soft Fijian language causing a considerable distortion of English names. Thus Woods, the eminent Notts player, is spoken about as "Utu," and the Australian Trumper as "Tiramba." The best Fijian bowler, "Ratu Pope," has been heard to say that he would die happy could he but scatter the wickets of the last named hero. Rumour says that he did not. The last Australian Eleven voyaged home by the All Red Route, which touches at Suva. Whilst there it had a scratch match with the local team, and gave it an afternoon's leather hunting.

Next door to the Fijian Islands is the Tongan Group, a somewhat conceited native State, which boasts of a King and Parliament of its own, modelled on the English style. The idea they have of their own importance may be judged by the announcement made at the commencement of the Franco-Prussian War, "that Tonga would remain strictly neutral." To understand the vagaries of that delightful spot, one should read "The Diversions

of a Prime Minister," Basil Thomson's charming book. Amongst other British institutions, cricket was adopted *con amor*, but not quite as we play it. Matches were made up, village against village, not confined to eleven a side. All the men were entitled to play and the fact that some villages were numerically stronger than others did not matter, beyond that it was so much the worse for the weaker. There was no gate money, but the games were made profitable to the local churches by a player being granted a fresh innings for a shilling, and as many as he could pay for, and the sums so derived were applied to pious uses. Kipling says that the Governor of Cabul did justice in the city gate, and that he who held the longer purse held the longer life; so in Tonga the richer the man the more his inningses. So great at one time became the fever for the game, that the villages, mostly dependent on agriculture for their existence, neglected their crops. There was no regulation as to the time of drawing the stumps and play went on as long as there was food enough, till at last many places were threatened by famine, and the High Court of Parliament had to pass an Act regulating the noble sport.

In the remoter parts of inland Fiji, too, away from the influence of white opinion, the game became very fantastic. There secret societies permeate native life. Though in many ways very childish, they are yet inimical to settled government and even before the advent of British rule disturbed the ancient authorities. They form a distinct subject, too long to be dealt with here, but strange to say they have become mixed up in an extraordinary manner with cricket. It was thought by some that they were the outcome of the work provided by the Devil for idle hands. When therefore many of the village youths took to cricket in some of the districts, their Commissioner hoped that they were finding an outlet for their superfluous energy, and, when requested, gladly consented to become president of the clubs and to subscribe to them. They blossomed forth with gorgeous uniforms, generally scarlet, and it was observed that nearly all the members had some sort of a badge on their right arm, corresponding somewhat to the stripes and chevrons of non-commissioned officers, though no two were alike. Inquiry elicited that the clubs had become sorts of guilds, with books, registers, codes of signals, etc., and that the badges were for the captain, or elder of the guild, as he was called, for the secretary, for the treasurer, for the chief of the outer circle and for the chief of the inner circle. The two latter were for the arrangement of the internal economy and external policy, in fact a Home Secretary and Secretary for Foreign Affairs. There was another office, too, which to the bewildered outsider could only be translated as "Lord

High Admiral." One could only at first think that the lines of Artemus Ward's celebrated volunteer corps were being followed, where to prevent jealousy all the members were Major-Generals.

Suspicion soon arose that the clubs were being used as a cloak for the secret societies, and in a district adjacent to that of the writer the members of one of them decided to emancipate themselves from the thrall of British rule. With a sincere imitation of it they elected a Governor, Chief Justice, Chief Secretary, and a host of other officials. But a kingdom divided against itself cannot stand and the weaker has to go to the wall, and the new régime retired awhile for meditation in the quiet and calm of the Provincial Gaol. Such are the ethics of Fijian life that imprisonment is not considered a disgrace. Gentlemen commit mistakes occasionally and expiate them by just punishment, emerging again into ordinary life whitewashed. Complainants and defendants then sit down together and partake of the "Burua," or mutual feast of atonement, after which it is considered mean to throw a gentleman's misfortunes into his face and taunt him as to his sojourn in gaol. Our present Governor, Sir Everard im Thurn, has stigmatised the Fijian prison system as savouring of comic opera, but it has its good points. Like the secret societies it is too long an affair to go into here.

The play of these clubs was as strange as their general administration and policy. At Nadarivatu, the Fijian Hill Station, and seat of the Commissioner responsible for the government of the inland mountain tribes, there has always been a small force of native constabulary under English officers, whose principal amusement is cricket. There, of course, the game is played *en règle*, and everything goes smoothly till the village clubs come up for matches. One of the set ideas of the latter is that the crack bowler is the bowler, and by prescriptive right. In fact, he is regarded as the Lord High Bowler, and as soon as the over is finished, he goes on again at the other end. He not infrequently shies and it was considered grossly unfair to score such efforts as no balls, and defeats were generally ascribed to the partial decisions of an adverse umpire. At a match not long ago a recent settler in the district, an English public school man, was put on to umpire, and proceeded according to established rules. His conduct very gravely disturbed the equanimity of the visiting team, and it was requested that one of their side, who really did understand the game, might replace him.

It would take too long to recount the many whimsicalities of pure native cricket, but the Fijian, taking him all round, is a good sportsman and only wants direction. He travels miles to attend our little race meeting and backs his choice for all he is worth. He is an excellent runner, swimmer and wrestler, and

fancies himself considerably with the gloves. The little cricket club generally have a set. But here again their form requires education. The public school boy mentioned above, in a journey across Viti Levu, found himself one night at a remote inland village with sporting proclivities. He was asked to put on the gloves with a local champion, and did so, and knocked him out almost at once. Then was asked if he would take on a couple at once, and again was victorious. A modest request to take on three was then suggested, but my friend thought he had done enough for the honour of the race. This was just after Johnson had had his turn up with Burns in Sydney. He passed through Suva on his return to America and was mobbed by admiring Fijians, elated by the victory of one of their own colour, many of whom are diligent readers of the papers and *au fait* with current events. The Jefferies fight has happened since I left Fiji, but doubtless the result is known to the native sportsmen.

A. BREWSTER-JOSKE.

## REVIEWS AND NOTICES.

**The Governance of Empire.** By P. A. SILBURN, D.S.O., Member of the Legislative Assembly of Natal. (*Longmans & Co.*: 9s. net.)

In this volume Mr. Silburn ranges over a wide field, which embraces the Achæan League, the Ætolian and Lycian Confederacies, the Roman Republic and Empire, the Venetian Republic, Switzerland, Russia, the German Empire and various other matters in addition to the subject which primarily interests him—that of the British Empire. We may as well confess that we have not kept company with the author through the whole of this journey, but have turned for enlightenment to Chapters XVI. and XVII. which, we learn from the Preface, are “confined to constructive policy.” The contents of these two chapters are unquestionably remarkable. Mr. Silburn starts with the now familiar lament about the indifference of the British Parliament and the British electorate to Imperial considerations. He is quite sure that all but “a very small number” of the House of Commons “are apt to think of the Colonies as these were in their beginning, as plantations or convict settlements,” and that this misconception is even more overwhelmingly prevalent among the electors. But though the British politician knows nothing about the Colonies—we are compelled to use the distasteful word, for the Crown Colonies as well as the Dominions are in question—Mr. Silburn, as a Colonial, of course knows all about British politicians. “The Liberal Ministers” (at the Conference of 1907) “had unfortunately misunderstood the outburst of loyalty on the part of the Colonies during the South African War as loyalty to the Conservatives and not to the Empire, and therefore

resented Colonial suggestions as undue interference." "Under the present political party-system in Great Britain, whichever party is in power, some portion of the Empire must suffer. When the Conservatives are called to office matters of official detail and office routine are left to the permanent officials, and Ministers concern themselves with questions of State. With a change of Ministry, and the Liberals taking office, there is naturally a change of policy. Imperial questions are handed over to the permanent heads of departments, and Ministers take into their own care questions of detail and of office routine." "A Liberal Government legislates for England and legislates well. The Empire it knows nothing of, nor does it care to know anything of it. Its leaders openly admit that territory outside of the United Kingdom is an unnecessary luxury." In view of all which we are pleasantly surprised to learn later on that "in Imperial questions there is no room for party differences and in their consideration Liberal and Conservative can, with honour to themselves, profit to the Empire, and confusion to the nation's enemies, unite on the common platform of Empire." Unfortunately, there are almost as many different ways of reconstituting the British Empire as there are of constructing tribal lays. There are, it seems, "eleven different opinions as to the best means of consolidating the Empire," emanating from "such statesmen or publicists as Mr. Chamberlain, Sir F. Pollock, Messrs. Deaken (? Deakin), B. Holland, Jehu Matthew, and R. Jebb," but "none of these suggested schemes have been seriously advocated." Mr. Silburn proceeds in all seriousness to advocate a twelfth, including an Imperial Legislature consisting of a single chamber of 216 persons, representing almost every part of the British Empire in the very widest acceptation of that term. (For example, Cyprus is to have three representatives—one less than Newfoundland—and it comes upon one almost as a shock to find that Egypt is left out.) But "the House of Lords and the oversea Legislatures corresponding to that Upper Chamber would still have the power of veto in Imperial legislation, as in National, Colonial, State or Provincial legislation." What would happen if a measure passed by the Imperial Senate was vetoed by the Federal Legislative Council of the Leeward Islands we are not quite clear. But it is, of course, conceivable that some other method of consolidating the Empire than that advocated by Mr. Silburn may be adopted. For the task of constitution-making is to be entrusted to a British Imperial Convention at which "the voting shall be by States and not be *per capita*." Every possession with not less than 100,000 inhabitants is to be separately represented at the convention, and smaller possessions are to be grouped for purposes of representation. "For instance, the tiny but strategically

important islands of St. Helena and Ascension would share a representative with their opposite neighbour British Gambia." (We wonder which would choose him, and why the Gambia, with a population of upwards of 150,000 is not allowed to stand on its own legs.) It will readily be realized that the United Kingdom and the self-governing Dominions will have a very small say in the matter under this scheme, and that the form of the constitution will practically be determined by the Crown Colonies and Protectorates. We find it impossible to forecast their probable conclusions, but we are indebted to Mr. Silburn for much entertainment.

---

**The Canadian Annual Review, 1909.** By J. CASTELL HOPKINS, F.S.S. (*Annual Review Publishing Co., Ltd., Toronto.*)

The *Review* relates with its usual vigour and completeness the political and social events which took place in or concerned Canada during 1909. The connection of the Dominion's politics with the affairs of the Empire is fully shown, and the question of Imperial and local defence looms large in these pages, reflecting the interest taken in it throughout Canada. The business connection with Great Britain is strikingly shown by the increase of British investments. It is frequently alleged in Canada that it is American capital that is developing the country, and that British investors are to blame for neglecting the opportunities. But the figures tell a very different story. "The increasing volume of British money finding its way into Canadian securities was one of the most marked developments of the year in an Imperial as well as purely Canadian sense. According to Mr. E. R. Wood, Vice-President of the Dominion Securities Corporation, Ltd., the chief personal factor in the amalgamation of the Dominion Steel & Coal Companies and a Toronto capitalist who had made a continuous study of this question, the total Canadian bond issues of 1909 were \$265,158,252 as compared with \$214,007,411 in 1908—itself a record year. Of the total figures in 1909 Great Britain took \$194,356,788 or over 74 per cent. as against \$165,455,081 or 84½ per cent. in 1908; the Dominion absorbed \$60,433,963 or 22½ per cent. as compared with \$24,585,140 in 1908 or 12½ per cent.; the United States took \$10,367,500 or 3.90 per cent. as compared with \$6,316,250 or 3¼ per cent. in 1908. These totals clearly illustrated the fact of Canada's dependence in a financial connection upon Great Britain, showed the means by which permanent capital was being obtained for Government, municipal and industrial undertakings, indicated the power at the base of Canadian exploitation of

resources, water-powers and transportation, and proved how greatly public services and private interests in Canada were at this time indebted to British financial backing."

The explanation of a prevalent misconception is that American capital is brought in more openly. There is considerable publicity and advertisement when an American factory or mine or office is started in the Dominion, while the English capital is put into municipal loans and large companies where its origin is lost so far as the public eye is concerned.

Internally Canada's course ran smoothly during the year: no racial and religious issues arose, the Provinces had no particular friction with the Dominion, and the tariff was not much discussed. This state of things indicates that work and trade were in a healthy condition, and the particulars of this prosperity are set out with remarkable clearness and a skilful combination of statistics and comment.

**Folk Stories from Southern Nigeria.** By ELPHINSTONE DAYRELL.

With an Introduction by Andrew Lang. (*Longmans, Green & Co.* : 4s. 6d. net.)

Mr. Dayrell deserves the gratitude both of the anthropologist and of the unlearned public for this collection of stories. Apart from their value as throwing light on the modes of thought of primitive man, folk tales are, upon the whole, the best tales in the world. One may call in witness the world-wide popularity of Grimm's stories, the scientific value of which has been wholly overshadowed by their abiding fascination over the minds of children of all races and all ages. In a learned introduction Mr. Andrew Lang points out many curious points of similarity between Mr. Dayrell's stories and the folk tales current elsewhere, and even without Mr. Lang's guidance the lay reader will find his recollections of tales from many sources re-awakened. In particular, he will recognise in this volume something like the raw material of the highly developed and much metamorphosed "Uncle Remus" cycle. The part played by animals in the stories is very large and they are made members of the general community of which human beings are a part in a curiously matter of fact way. The tortoise generally plays the part of Brer Rabbit, and his resourcefulness does credit to the imaginative powers of Southern Nigerian man. Many of the stories have a "moral," and most of them profess to give a historical explanation of some natural phenomenon or human custom—why bats only come out at night, why the sun and moon

live in the sky, why dead people are buried, etc., etc. As is to be expected from their origin, many of the tales are marked by an extreme of cold-blooded ferocity, and there are many odd superstitions about Ju Ju trees and the like. Mr. Dayrell shows good judgment in presenting the stories in the simplest possible narrative form, and economizing his explanations.

---

### Cotton Growing in German Colonies.

We have received from the Kolonial Wirthschaftliches Komitee in Berlin a copy of a second enlarged and improved edition of Professor Zimmermann's *Anleitung für die Baumwollkultur in den Deutschen Kolonien*. A smaller popular handbook specially adapted to the requirements of German East Africa is also published.

---

### Sierra Leone Forests. (*Printed by Waterlow & Sons Limited.*)

A report by Mr. A. H. Unwin contains detailed information on the valuable resources of the Colony in timber. The industry is at present carried on in a wasteful and costly manner by hand-sawing in pits, and there seems to be an opening for private enterprise which would provide large saw-mills with planing machines, using water power where possible.

## BUSINESS NOTES.

Prosperous conditions continue to prevail through the Empire, and there is a marked freedom from those political troubles which tend to disturb credit and unsettle enterprise. The immediate future will be characterised by a considerable amount of railway work. Canada has a large programme in hand, and a big development is coming on in Australia. The purchases on these accounts will be of great benefit to British manufacturers, but this is not all to the good from the point of view of the Colonies, as large demands tend of course to raise prices and delay deliveries.

The Crown Colonies, on the whole, are doing well. The rubber boom has subsided so far as inflated prices for shares are concerned, but the formation of companies goes on apace. The new Straits Settlements agency for supplying information to intending cultivators will be now available, and investors or planters will have the great advantage of reliable advice as to the estates in this headquarters of the planting industry. Such developments make it important to push on survey work, and in the past year considerable progress has been made in the Cape, Orange River, East Africa, Uganda and Northern Nigeria. Many other Colonies are backward in this matter. The Colonial Office have made new arrangements for the selection of candidates for junior survey appointments. (Cd. 4,964-18.)

A number of applications for oil-fields concessions have been dealt with by the Trinidad Government, and there is strong financial support for these undertakings.

The favourable price of sugar has stimulated production, and in Jamaica a revival of the industry is beginning in real earnest. The banana industry is also progressing steadily in this Colony

and it is anticipated that in no long time the exports will exceed twenty million stems per annum. Fortunately the island is free from the banana disease which is said to be making alarming progress in Costa Rica.

Among the loud claims of fashionable products the merits of the cocoanut are in danger of being overlooked. This is not being boomed, but it is one of the most satisfactory in results of all tropical products. It combines well with bananas, as it relieves the subsoil of moisture. The dessicated kernel is in great demand in confectionery, and the rope and matting is profitable. It is not generally realised that the value of the cocoanut exports from Ceylon is nearly a quarter of the whole export, and capitalists may do much worse than turn their attention to this safe product.

---

### Wheat.

Wheat of fine quality has been produced in East Africa and, it is expected, will command a ready sale and the highest prices in this country. Very promising wheat has also been grown about Kano and Zaria in Northern Nigeria. Considerable exports from both sides may be expected before long, and if care is taken at this early stage to select and adhere to the most suitable varieties there will be a great future for this crop.

The breeding of wheat to suit South African conditions has but just begun. In Australia it was taken in hand years ago, and the story of one particular variety, which has come very prominently to the front lately—the Federation Wheat—is so encouraging that it should be widely known. Federation wheat, which has proved so successful during the present year throughout the Australian States—South Australia and Victoria especially—is a variety that was artificially bred by Mr. Farrer, the late wheat experimentalist to the New South Wales Department of Agriculture, about twelve years ago. It was first widely tested in 1903-4, when the plots on the Government Farm at Wagga yielded 35½ bushels to the acre. In the following year these results were published by the Victorian Department, and the wheat was introduced into the experimental plots of the State. So rapid has been the advance of the new variety in the estimation of farmers that probably one-fourth of all the wheat in Victoria this year is Federation. As the yield is at least three or four bushels to the acre above that of all other varieties, the benefit in that State alone during the year from the work of the late Mr. Farrer may be estimated at 1,500,000 bushels of wheat,

representing a cash value to the farmer of £250,000—a remarkable result for a scientific man to accomplish in one season. That is the epitome given by the Victorian Director of Agriculture (Dr. Cherry), who says:—"The question of whether the present wheat harvest will realise the official forecast of 28,500,000 bushels depends to a large extent on the way that Federation may have stood the test of an unfavourable winter's growth. The variety has proved its ability to withstand drought, but the present year is the first which has offered the conditions for testing whether it can successfully pass through the test of an abnormally wet winter. Up to the present the returns received are all in its favour. Returns of 20 bushels to the acre in the Mallee and 35 bushels in the best parts of the Wimmera are being recorded."

---

### Cape Wines.

During the last three years attempts have been made to export these light white and red wines in wood to Europe. It is generally stated that light wines could not be sent in wood to Europe, as they turn bad and get unfit for consumption. This belief is so general that many who heard of the intention of the Government of testing the European market and sending light wines to London and Hamburg strongly disapproved of this plan, the result of which, they held, must be disastrous. But there is no reason whatever why sound light wines put in sound seasoned casks should not arrive in perfect condition in Europe. The experiment has been made. The wines sent were one year old, Hermitage and Sauvignon Blanc, from Constantia and Klassenbosch, Cape Peninsula. The wines were perfectly sound, and were put in sound, well-seasoned casks. They arrived at Southampton and Hamburg in perfect condition, and were pronounced by experts to be superior to Australian wines. The European market is, however, flooded with light red and white wines from Algeria and other wine-producing countries to such an enormous extent that the price offered for the Cape wines was only two shillings to two shillings and threepence per gallon in wood. A small amount of this wine was sold, but the remainder was returned to the Cape. Here they arrived in excellent condition, and very much improved in bouquet as well as in taste by the journey of twelve thousand miles by sea, in addition to some rough handling in Europe. There is no opening for light Cape wines in the European market, which is overstocked with light wines sent from all wine-producing countries. The best chance is for a sweet wine and this the Cape could no doubt produce.

**Fruit.**

The large interests of many Colonies in this industry make it important to study the causes of decay in transit, and some recent investigations in America are valuable. Decay was usually attributed by growers to weather and the railroads and steamships, in other words to conditions which affected the fruit after it has been packed. But the truth is that the trouble originates at home. It is rough picking, careless handling and antiquated packing that are to blame. The fruit should, as soon as picked, be cooled to the lowest temperature that it can stand without injury.

Efforts are being made to introduce Cape fruit into America, and in the period January-April it would be in a favourable position. It would, however, have to be shipped viâ the United Kingdom as the ships from America to the Cape do not return direct, and much depends on the quickness of transshipment and the steamship rates. The Americans are acquiring a good deal of land in South America for the purpose of fruit growing, and these companies will probably have a good deal of influence with the market. It may be suggested that the best way of increasing the Cape trade would be to get one of the collecting companies to take an interest in it.

---

**Oil.**

From Canada to Brunei reports come in of the discovery of oil and the production is sure to increase materially. Not much is yet heard of South Africa in this connection, but there are clear indications in Cape Colony and Orange River Colony that oil can be obtained, and at any time a large production may spring up. There is no particular advance to chronicle in West Africa, and the many people who are in the field might do well to join hands and see what they can do with the best concerted counsel.

---

**Tea.**

Planters will be well advised to consider the possibilities of Nyasaland for this product, though the area suitable for it is limited. It is questionable if the yield will be so heavy as on the best Ceylon plantations, but experiments so far indicate from 350 to 400 lbs. per acre; the quality is certainly superior to low country Ceylon judging by past season's prices, which varied between 5d. and 7d. per lb. in London. Even with a smaller yield than Ceylon it points to be a most profitable crop for Nyasaland as

labour is at least 50 per cent. cheaper; the natives like the work and many of the children exhibit considerable activity in picking. The tea area is within 20 miles of the Shire Highlands Railway, and tea is carried to London for 123s. per ton.

---

### Cotton.

In a country with a short growing season, like Nyasaland, the branching character of the plants has a great influence on the ripening of the crop, and therefore the yield per acre depends in no small degree on the type of plant grown. Under those conditions it is necessary to take advantage of every character that leads to early maturity, as heaviest yields are obtained from plants which carry many fruiting laterals arranged around the main stem in such a manner as to allow the maximum amount of sunlight to reach the entire plant without shading its neighbours or obstructing tillage operations necessary for the best growth of the crop. Plants with extra long horizontal or prostrate lower branches should be avoided as they interfere with cultivation; if they are fruiting branches the lower bolls open late and the cotton is liable to soil stain; if they are purely vegetative branches they receive insufficient light for maximum carbon assimilation (*i.e.*, starch making). Plants with dense upper foliage should also be avoided as they generally shed a large percentage of their lower bolls.

---

### Wireless Telegraphy.

A contract has been given to Marconi's Wireless Telegraph Co., Ltd., for the erection of one 5 K.W. Station at Suva, Fiji, and two 1½ K.W. Stations at Savu Savu and Vuna Point. The contract price is £6,410, the Government providing the buildings and the foundations for the masts and stay anchors.

The tenders on this occasion were nearer in price to one another than on previous occasions, indicating that the industry is becoming more precise.

---

### Motor Transport.

Two Wolseley-Siddeley cars, bought in 1908, have given great satisfaction in Northern Nigeria, running very well on rough roads during the dry season. The circulating water pipes, however, were of too small diameter; they cannot be too large in a hot country. The petrol tank is in the rear, and the joints of the

long air pressure and petrol pipes were frequently giving way under the severe bumping on rough roads; for such purposes the tank should be near the carburetter.

There is no doubt that the increasing use of motors is developing traffic in West Africa, and encouraging the natives to improve the roads.

---

An American company is maintaining a regular daily service, carrying passengers and mails between Kingston and Port Antonio. They have fifteen cars, three being for twelve passengers, and charge 3d. per mile. The business done has been good, and where, as in Jamaica, the roads are good, such enterprises are sure to increase.

---

#### Motor Transport Service, Ibadan-Oyo.

Paraffin is still used to run the motors on but the advantage of this fuel is not so great now as formerly. Petrol can be landed at Ibadan at 15·3 pence per gallon.

Continual trouble was experienced with all tyres used until the Shrewsbury & Challiner Band type were obtained. These tyres and the method of fitting are mentioned in the 1908 report. The first one fitted (July, 1909) to a wooden artillery rear wheel ran over 7,000 miles without trouble, and it was only after several weeks of the dry harmattan season that it was necessary to fit in new lagging of increased thickness to take up shrinkage. This tyre should complete its guaranteed mileage.

For consignments of over 10 cwt. the present rate is 33s. from Ibadan to Oyo, and the return is 25s. per ton; it is therefore possible, if the vans are fully loaded each way, to earn:—

No. 1 van	...	(20 cwt.)	58s. 0d. or 10·5 pence per mile.
Nos. 2, 3, 4 van		(30 cwt.)	87s. 0d. ,, 15·81 ,, ,, ,,
No. 5 van	...	(45 cwt.)	130s. 6d. ,, 23·71 ,, ,, ,,

The year's working showed a loss, but this was largely due to the condition of the roads. The transport is likely to encourage European firms to start business in the places served.

---

#### Motor Fire Engines.

The increase in the adoption of motor fire apparatus by the leading fire brigades in Great Britain and abroad has been quite remarkable during the last two or three years. One maker alone

(the firm of Merryweather & Sons, at Greenwich) have built nearly 150 machines. The latest engines completed by Messrs. Merryweather, which have just been supplied to the Salford Corporation, are two patent "Hatfield" petrol motor fire engines, each of a pumping capacity of 450 gallons per minute, and with arrangements for carrying a 60 ft. escape. At the tests of these engines at Salford, when lifting water from a total depth of 24 ft., pressures of 140 lbs. to the square inch were maintained on jets 1 in. in diameter. With a single jet  $1\frac{3}{8}$  in. in diameter a pump pressure of 120 lbs. to the square inch was maintained through 25 yards of 4 in. diameter hose. The motors had an R.A.C. rating of 52 h.p., and the results obtained, we believe, constitute a record for efficiency for this pump. The machines ran without a hitch from start to finish and with an absence of vibration that was remarkable considering the power of the engine. The machines are of specially strong construction to meet the exigencies of fire brigade work, and can travel at a speed of 30 miles an hour on the level. Two similar machines, fitted with front wheel brakes and latest improvements, have just been delivered to the London Fire Brigade.

---

### Storage Batteries in Hot Climates.

Mr. E. P. Harrison, of the Physical Laboratory, Presidency College, Calcutta, refers to the difficulty experienced in hot countries in keeping small accumulators in working order, and points out that this is probably due to the cells being filled with dilute acid of density 1.190 at a temperature of 30 degrees or 35 degrees Centigrade. While this is a proper density to use in a climate where the temperature is 15 degrees to 20 degrees Centigrade, corresponding to a 20 per cent. mixture, it is too high for a hot climate, where it really represents a 23 per cent. mixture; a density of 1.170 or even 1.150 is more suitable in hot climates.

---

### The Purification of Muddy Waters.

Much of the water available in the Colonies is rain water stored in open tanks with puddled clay embankments and floors. Such water is practically never clean, but generally discoloured, with a fine suspension of mud.

This mud is so finely divided that it does not sink under the force of gravity nor can it be separated under the greater force exerted by the centrifugal machine. In the language of physical

chemists, it is in a condition of "colloidal suspension," and its separation from the water requires either an effective filter, or the use of a chemical reagent.

An effective filter is, however, generally speaking, a slow filter, and will not allow large volumes of water to pass in short intervals of time. Further, they are costly to buy, and unless treated with care, and regularly cleaned, they may signally fail to purify water which contains harmful bacteria.

In fact, a badly cared for filter may be a source of actual danger, for bacteria may thrive in countless numbers amongst the material collected in the filter, and may later be washed through into the filtered water.

By the second process of purification, namely, chemical precipitation, no expensive initial plant is required, large volumes of water may be satisfactorily handled, and any one with good commonsense can control the process, whereas the management of a filter requires a skilled and intelligent man.

If arrangements can be made for a cheap supply, it appears from experiments conducted in Victoria that treatment by chloride of iron is the best. A tank of 850 gallons was practically completely purified by the addition of  $\frac{1}{2}$  lb. and  $\frac{1}{16}$  lb. of iron chloride in solution.

The ideal substance would be a *cheap* salt of aluminium, iron, or chromium. From the practical point of view, the cheapness is almost as important as the chemical-efficiency, and consequently for actual use only the following need be named, viz., alum, chloride of iron, lime. The last of these is able to compete only on account of its cheapness. It is especially to be noted that it is not nearly so "brilliant" in its action as either alum or chloride of iron. It is, however, a practical substance to use.

In choosing between alum and chloride of iron, the price is at first sight in favour of the former. Weight for weight, however, 1 lb. of chloride of iron is worth 2 lbs. of alum, and this fact, together with its easy solubility, turns the scale in its favour.

The "brilliance" of the action of iron chloride, that is, the efficiency with which it acts, the rapidity with which it causes the mud to settle, and the ease with which it can be handled owing to its solubility, make it excellent. It is not merely harmless. It is more, it is a most valuable mineral constituent for all animals. There is consequently a distinct gain, even if too much is added to the water.

The added chemical (if not in larger quantity than required) is thrown out with the mud. The precipitated mud will settle down through seven feet of water in a single night by the ordinary force of gravity.

Clean waters so obtained are valuable in butter factories and dairies, or for use in steam engines. Also, stock are the better for a supply of clean, rather than dirty water, and a liberal supply of clean water is acceptable for domestic purposes.

The process is perfectly simple. Thus in Victoria a small water hold, containing an estimated 1,000 gallons of a thick and dirty muddy water was treated on the evening of 2nd May with 1 lb. of iron chloride. The concentrated iron chloride solution was diluted, and just thrown out over the surface of the pond, keeping the distribution as uniform as possible. The water was not stirred at all, though it would have been more advisable to have stirred the surface layers, so as to insure a regular distribution of the chemical.

Next morning, 3rd May, the water was clean, and every leaf and twig could be seen on the bottom of the tank.

---

### Reinforced Concrete.

A Supplement to the *Jamaica Gazette* (28th July) contains a valuable report by Mr. A. E. H. Herschel on earthquake-resisting construction. The case of an earth fall just under a building could only be met by building on a small scale and on the steel box plan. But this very rarely happens. The common case is that of vibrations, the effect of which is to bend some parts of a structure, and this can be largely provided against. Mr. Herschel sets out the mechanical requirements and sums up in favour of reinforced concrete.

“ This is the only building material which really satisfies all the ‘ requirements ’ mentioned above. Its strength *begins* where the strength of ordinary unreinforced brick work *ends* for in reinforced concrete no allowance is made for the strength of cement in tension. The steel takes all of the tensional stresses, so this material combines the durability and fire resisting qualities of masonry with the tensional strength and ductility of steel, and above this it possesses certain qualities which are peculiarly its own. It has greater resilience—or power to resume its original shape quickly—than any other building material and it can be bent without failing to an extent which would surprise anyone who has not seen it.

“ It is truly monolithic, that is to say it has no joints, and it forms a light building for the loads it can carry. As regards its durability, all that can be said is that it appears to get stronger the older it is, and this process appears to go on for an indefinite period.

“ I am not clear that it makes such an healthy building as one with hollow walls, but there is not much evidence either way.

“ The greatest objection to it is that after the concrete has been cast it is impossible to say whether the steel is in the right place, or even whether there is any steel in it at all.

“ As regards the best material to be used for concrete walls, I am of opinion that a 1-3-6 mixture with say 3 (of the six parts of aggregate) of brick and 3 of fine gravel gives the toughest and most satisfactory mixture for this climate.

“ There are a few points in connection with reinforced concrete construction to which attention may well be called here.

“ In order to get the most out of the advantages offered by reinforced concrete, the greatest care should be taken to strengthen those points which are subjected to concentrated loads. This may be done in a hundred different ways as, for instance, by the use of extra rods or links or stirrups hooked across the main reinforcing rods to tie them more firmly together where there is any chance of a shock tearing the wall or pier asunder. But the main point is to see that whatever extra reinforcement is designed to be used is actually put in.

“ These small additions may seem trivial, but they are just those little details which may make the whole difference in the day of trial, and they can only be secured by the closest supervision before *and while* the concrete is being placed in position. I cannot speak too strongly on the need for special supervision where reinforced concrete is concerned. Without supervision it may be the most dangerous material, and owners are particularly warned that failure on their part to provide efficient supervision may render all the trouble and money they have spent on their buildings useless. Reinforced concrete must either be done well or not done at all. It is not a material which it is safe to entrust to careless or inexperienced hands.”

---

### Ferro-concrete in Mauritius.

The construction in ferro-concrete of the Bacteriological Laboratory and of the new Lighthouse has been successfully carried out and has resulted in appreciable economy. The cost of construction has been reduced and, owing to the solid nature of the structures, the cost of repairs will be reduced to a minimum. The designs were made by Mr. de Segrais, who has the rare reputation of keeping within his estimates.

### Roofing Tiles.

The special articles which are now being extensively used in the Colonies afford a striking illustration of the effects of Mr. Lloyd George's Patents Act of 1907. The Eternit tiles were made by an Austrian firm, and a patent for them was taken out in this country by their exclusive licensees, a Belgian company, but the process of manufacture was carried out entirely abroad. In an action brought for the revocation of the patent it was held that the patentee could not show cause for his "inaction." The only reason for it seems to have been that cheaper labour could be obtained abroad. "From the evidence it appears that there is little, if any, difference in the prices at home and abroad of the materials used or in the facilities for obtaining them, and the only other reason which has been alleged why the process can be more profitably carried on in Belgium, Germany, and France, than in the United Kingdom, is that the wages of the work-people in those countries, who in the carrying out of the patented process now under consideration for the most part are unskilled labourers, are lower than in England. If this reason is an insuperable bar to the introduction of the industry to this country, it is very difficult to understand how many industries which are carried on successfully in the United Kingdom continue to be so carried on."

That the manufacture can be carried out here is shown by the enterprise of Bell's United Asbestos Co., Ltd.

---

### Alcohol from Fibre Plants.

There are a number of plants which yield both fibres and juices, and these juices contain a large amount of sugar, which renders them very suitable for the distillation of alcohol.

The denaturing material mainly used is Methyl Alcohol; there are many other materials (about thirty) which are equally effective. It is customary to add to 100 parts, by volume, of alcohol (not less than 90 per cent. strength), ten parts of approved methyl (wood alcohol) and one-half of one part of approved benzine. This blend or mixture is classed by leading Governments as completely denatured alcohol.

Industrial alcohol is now being increasingly used with great efficiency and economy in many parts. The leaves and stems grow in country districts, the industrial alcohol is produced there, and is consequently very cheap. All kinds of engines, stationary, portable, for motors, for road and water transport, etc., can be

driven by it. It is used for many industrial purposes; also for agriculture, such as for ploughing, harvesting, mowing, pumping water, sawing timber, grinding grain, etc.

Industrial alcohol is also being increasingly used for heating purposes; it burns with a blue flame, intensely hot and without smoke. Its odour is not disagreeable, rather the contrary; and consequently it is well adapted for heating houses and premises of all kinds, for cooking, coffee roasting, etc. Many important improvements have, as a consequence, been recently made in the construction of heating apparatus, cooking and other stoves, by adapting them for burning alcohol in a thoroughly practical and economical manner.

To produce alcohol the leaves and stems are first passed through a special crushing and juice-extracting machine, which performs three operations. It slits the leaves into longitudinal strips, the smaller ones being slit up in the centre, while the larger ones are slit into four strips. In passing through its three pairs of large brass rollers the leaves and stems are not only crushed with great pressure, but the upper and lower skins are simultaneously scraped by a special arrangement, so as to facilitate the flow of juice and the subsequent extraction of the fibres. The juice, after being prepared, is then distilled. Special continuous-working steam stills are used for distilling the alcohol in one operation in a simple and economical manner with a minimum of fuel and water. These stills are simple in construction, easy to erect, and capable of being worked by an ordinary intelligent mechanic. They exhaust entirely all the spirit from the wash, and produce alcohol of the highest commercial strength. The cost of production is small.

---

### Condensed Milk.

There is so large a demand for this article from many Colonies that an analysis published by the Cape Agricultural Department is interesting. Most of the brands are remarkable for a large proportion of sugar and a small proportion of milk. Thus one of the best milks of its kind contains 81·22 total solids, of which 70·22 represent non-fat and 11·00 fat; the rest is water. The remark is added that "It will be seen that such condensed milks, diluted according to the directions on the label, compare very unfavourably with the average milk sold about the Cape Town streets (adulterated milks included), and when we remember that three-fourths of the total solids in the condensed milk consist of cane sugar, we begin to

understand why infants should starve if continually fed on what is little better than a mixture of sugar and water."

A lactometer test of milk is of no value by itself. The most rapid test is that of separating the fat by means of a Gerbher or Liffman-Beam apparatus and taking the specific gravity by a Westphal balance. A full scientific analysis includes an examination for the presence of chemical preservatives such as boric acid.

---

### Manufacture of Steel from Scrap Iron.

To commercially produce iron and steel on a large scale the essentials are:—

- (1) Cheap supplies of suitable raw materials, such as iron ore, coke, and limestone;
- (2) Good and cheap labour;
- (3) Markets which can readily absorb a large output.

The cost is usually prohibitive unless the production is on a large scale. But in many places scrap iron accumulates in considerable quantity, and might advantageously be converted into steel by an electric plant. The cost of such a plant would be comparatively small, and the finished products would largely consist of high priced materials offering a fair margin of profit. Railways and mines require considerable quantities of steel castings, drill steel, shoes and dies, small forgings, etc., all of which could be produced from scrap quite equal in quality to the articles at present imported. To economically work up the scrap it is essential that a process should be adopted which can be worked independent of any imported material, either pig iron or scrap; and an electric steel furnace is, under all the circumstances, by far the most suitable and the one which will give the best results in actual practice.

The electric furnace for the manufacture of steel from scrap has long passed out of the experimental stage, and the Heroult furnace has been commercially producing high-class steel from very miscellaneous scrap for the past eight years; various other electric furnaces are also giving excellent commercial results.

Gaseous fuel is not employed in the electric furnace, so there is no danger of sulphur being absorbed by the steel, and the process therefore especially lends itself to the manufacture of high-class steel.

With all gas-fired open hearth furnaces there is always more or less trouble caused by the steel absorbing sulphur from the

gases, and this would be especially troublesome when using comparatively inferior coals such as are generally available in the Colonies.

---

### A Simple Test for Tin Ore.

The *Queensland Mining Journal* describes an excellent test for tin ore in "Mineral Resources for 1908," which method, on account of its simplicity, deserves to be widely known.

A piece of the suspected mineral is treated with zinc and dilute hydrochloric or sulphuric acid, preferably the former, when, if tin oxide, a coating of metallic tin soon appears on the fragment. Some of the hydrogen gas, given off by the action of the acid on the zinc, unites with the oxygen of the tin ore, to form water, leaving metallic tin on the surface of the specimen. The mineral and the zinc should be in close contact, consequently granulated zinc is recommended, though the present writer finds that zinc shavings also work well.

No heat being required, the test can be made in an ordinary china cup, and, after putting some zinc under and round the fragment, a little water may be added and then enough hydrochloric acid to cause a vigorous action. In a few minutes the liquid can be poured off and the mineral washed in water, when, if cassiterite or tin oxide, a grayish metallic coating will be seen, which, by rubbing on the hand or with a soft cloth, soon becomes bright. Care must be taken to have an excess of zinc present, or to pour off the liquid before all the zinc is dissolved, otherwise, the acid, if in excess after the zinc is all in solution, will in course of time dissolve the coating of tin. Supposed tin minerals are often tested on charcoal with a blowpipe, but the above method is simpler, and further, there is no necessity to reduce a specimen to powder, as, in some of the writer's experiments, good results were obtained with pieces of cassiterite three-quarters of an inch in diameter. Tin ore alone is infusible before the blowpipe, and is proof against all acids, hydrogen being the active agent in the test just described.

---

### Corrosion of Metals.

Cases of corrosion are continually occurring which cannot be accounted for on the grounds of the wrong alloy, deleterious impurity, or unsound structure. The following observations by a well-known firm, which has given much attention to the subject,

throw light on the causes of these phenomena and the possible remedies:—

“All ordinary metals are corrodible, and tubes made of such metals will, under adverse conditions, fail rapidly. Our investigations have been convincing that rapid corrosion of condenser tubes is not due to faults either in composition or structure of the tubes, but entirely to the severe corrosive influences, chemical and electric, to which surface condensers are subjected. Acids, whether mineral or organic, alkalis, and other constituents of polluted water are corrodents; but we find chlorine, in its free or other active state, liberated from saline water by chemical and electrolytic action to be one of the principal causes of the trouble. The corrosive action attacks both the copper and the zinc of brass tubes. Sometimes the action on the brass appears to be mainly operative on the zinc, which form of corrosion is described as “dezincification,” and is of common occurrence in ships’ brass underwater fittings generally.

“In vessels frequenting docks, harbours, estuaries, and canals, where the water contains impurities, both in suspension and solution, the corrosion and pitting of the condenser tubes is severe; in some cases especially so. In ships which avoid these foul waters and sail mostly in the ocean the corrosion is comparatively slight, and takes place fairly evenly over the whole surface of the tubes, the life of which is thus greatly prolonged, as the destructive pitting is largely avoided. Ships leaving saline water and entering brackish water, and the reverse, have been known to set up a galvanic action in the condenser tubes, provoking corrosion. If the condensers were working in the best possible condition, and in pure water, the life of the tubes would be prolonged indefinitely.

“Means for minimising the corrosion of tubes are sometimes employed, such as suspending slabs of zinc or other suitable metal in the water spaces of the condenser. The corrodent attacks the metal slabs, and this diminishes the severity of its action on the tubes, ferrules, and other parts of the condenser.

“To give favourable results condenser tubes must be worked under good management, and be kept clean and free from deposits of mud, seaweed, and other matter found in neglected condensers. They must not be subject to stray currents of electricity, and no deposited particles of metal, metallic oxides, or carbonaceous matter entering with the cooling water should be allowed to remain on the surface of the tube. The galvanic action caused by these particles resting on the tubes decomposes the saline water surrounding the particles, liberates the active element chlorine, which speedily attacks the tube with the too familiar results. In practically all cases of pitting and per-

foration which we have examined it was found that the metal had mainly been converted into oxy- or basic chlorides of the metal composing the tube, thus giving conclusive evidence that chlorine is the most active corrosive agent.

“ When new tubes are fitted in a condenser, special vigilance should be observed as owing to their clean bright metallic surfaces they are then naturally in a most susceptible condition for the attack of any corrosive substance which comes into contact with them. During use, at an early stage in their life, some tubes become covered internally with a thin scale of lime or other salts deposited from ordinary sea water, and such an internal covering is said to protect the tubes against corrosion, even in the event of the condenser afterwards using impure river or harbour water. Therefore, if means are taken to ensure that the tubes receive and retain a slight deposit of lime salts they should give a longer life. This internal deposit or lining need only be slight, so that it does not appreciably affect the heat conductivity of the tubes, and such a protective deposit could be induced on the tubes by the occasional addition of lime or other suitable scale forming salts to the cooling water as it passes into the condenser.

“ In the condenser tubes are often found quantities of oxide of iron proceeding from the corrosion of the cast iron fittings. This oxide always contains graphitic carbon, and sometimes forms a complete lining to the tube. Minute particles of metallic scale or carbonaceous matter are sometimes found in the centre of the base of the oxy-chloride pustules formed on the condenser tubes by corrosion, and which have ultimately resulted in the formation of pit holes in the tube.

“ Particles of foreign matter naturally accumulate on the lower interior surface of the tube about the middle of its length, which, when the engines are at rest, and especially if the tubes sag at all, is often covered with stagnant saline or other foul water, thus accounting for the corrosion and pitting of the tubes being most severe on their lower interior surfaces. This may be minimized by fixing the condenser in an inclined position. In cases where this pitting was severe a remedy was found by passing the tubes through holes in a diaphragm plate which supported the middle portion of the tubes, thus preventing the tubes from sagging and the water stagnating in them, and also reducing injurious vibration of the tubes. It has been found beneficial to flush out the tubes frequently with clean water, and so remove any obnoxious matter remaining. Condensers should be fitted with discharge cocks, so as to give a ready means for draining the tubes.

“The chemical and galvanic action to which tubes are subject in a condenser is greatly accelerated by heat. In a condenser with a feeble circulation of cooling water, or one giving a defective vacuum, the corrosion is rapid owing to the increased temperature. The supply of cooling water should be abundant and forced rapidly through the tubes. This helps materially to keep the tubes cool and free from the lodgment of noxious deposited particles. Owing mainly to defective circulation of the cooling water and unequal distribution of the steam, the corrosion in the same set of tubes may differ greatly, some being hardly affected whilst others are destroyed by pitting. If all had received a full and rapid supply of cooling water, and the steam entering the condenser had been equally distributed amongst the tubes, then a good vacuum would have been obtained and rapid corrosion would have been greatly reduced.

“In some condensers means have been taken to separate air from the incoming circulation cooling water with beneficial results. No pockets or cavities should exist where air can collect in the water spaces of the condenser.

“If a condenser becomes connected to or influenced by any electrical current, as sometimes happens, the corrosion becomes rapid. We ourselves have experienced this active corrosion when tanks and tubes have been accidentally connected with some source of electricity. This acceleration of corrosion by electricity can be demonstrated experimentally by immersing wholly or partially a small piece of tube in salt water and passing a current of electricity through the tube and solution to the metal vessel containing the tube, when a rapid corrosion will be set up.

“It occurs sometimes, owing to imperfect packing of the stuffing boxes or glands of the tube plates, that the tubes are loose in their end bearings; this wears the ends of the tubes, which is accelerated if impure or rancid grease is used in the packing.

“We always find that in cases of rapid failure of the whole or part of a set of tubes in a condenser, other similar tubes, amounting to many thousands, give excellent results in other condensers; yet all these tubes, both those that failed and those that gave a long life, were manufactured concurrently from the same castings, made from the same alloys, and of precisely the same process of manufacture. Hence no guarantee, implied or expressed, can be given as to the durability of condenser tubes or as to their suitability for special conditions, even if such conditions are known to us.

“Brass tubes of 70 per cent. copper and 30 per cent. zinc, the alloy now usually supplied, yield, under good management and conditions, a long life, sometimes twenty years or more. The substitution of one per cent. of tin for one of the 30 parts of zinc,

as used by the British Navy, is thought by many to give better results. Tubes composed of various alloys of copper have been tried. Amongst these are copper-nickel tubes, the cost of which is, however, much greater than that of brass. Their durability under adverse conditions, and their galvanic action with the other metals of the condenser are yet unproved.

“ To compare the life of sets of tubes of the same alloy as a means of ascertaining their quality is entirely misleading, on the other hand it is of value as showing the working conditions and arrangement of different condensers.

“ An experienced authority writes that to secure good results in a condenser ‘ eternal vigilance and a good supply of spare tubes are necessary.’ ”

---

### **Beacon Lights.**

If a light of small intensity satisfies the requirements, a beacon with acetylene illuminant is suitable: it is self-contained and one holding a charge of 1,500 lbs. of carbide will maintain an occulting light of 140 candles intensity for about six months without recharging. Such a beacon is made by the International Marine Signal Company and has been recommended by Trinity House: price about £425. But the lamp should be cleaned every week.

---

### **Jetties.**

The General Manager of the Gold Coast Government Railways, while on a visit to Togoland, was much struck with the jetty, which he describes as a striking example of engineering skill and daring. He refers to the light character of the structure, offering the least possible resistance to the wave-stroke, and the boldness of the conception in reaching through a heavy broken surf into deep water within a few cable lengths of the ships' anchorage. There is ordinarily a depth of 24 feet under the head of the jetty. The cost was 1½ million marks, or £70,000, a very low figure for such an achievement.

---

### **Light Draught Steamers.**

Turbine machinery is lighter than reciprocating engines, and the advantage increases in proportion to power developed; it also requires much less height. These considerations make it suitable on a light draught.

Water tube boilers also are advantageous in the same circumstances, as less weight is required in proportion to the horse power. It is true that they require careful and skilled management, but on comparatively short passages they should give satisfactory results. Furthermore, a great control of steam production is possible and economy of fuel is secured.

---

### **Decorticating Machine.**

Messrs. John Downham & Co. have produced a machine which is practically two of the old beater type machines, combined with crushing rolls and feeding apparatus. This arrangement dispenses with handling the leaves after crushing, and this, besides saving labour, avoids the painful effects which the acrid juices have on the operators' skins and which make it necessary for them to work in relays. The firm claim to pass through the machine from 120,000 to 150,000 leaves per ten hours, and to extract as much as 97 per cent. to 98 per cent. of the available fibre; and from an examination which has been made, it appears likely that this claim is justifiable. The machine is of good solid construction and free from vibration. The price is £600, the same as of the "World's Decorticator," of the World's Fibres Machinery Corporation, Ltd. This is a much lighter machine and of much smaller capacity, but it is claimed for it that the fibre being produced by combing is in no way injured.

---

### **Canvas Tents.**

The Willesden proofing process is a very favourite one, but it seems probable that it shortens the life of canvas. We have seen a report by an expert to the effect that it extracts the natural oil in the canvas, and that the proofing agent, which is applied only to the surface and is very friable, rapidly wears off and leaves the canvas unprotected. There is another process which, we understand, has been adopted by the War Office, but it is more expensive.

---

### **Waterways.**

In addition to dredging, it is desirable to increase the depth of water by reducing excessive breadth, and a cheap but effective way of doing this is by lining the banks with low walls of wicker-work. These can easily be constructed by natives from bamboos. Banks of sand are then formed and if necessary the walls can be shifted further in.

### Gas Engines and Fuel.

Mr. Kenneth Crossley, chairman of directors of Messrs. Crossley Bros., Ltd., in the course of a speech at the thirteenth annual general meeting of that concern, held in Manchester, remarked that, after many years of experiments, they had lately brought out various types of suction gas plants to work on all sorts of different fuels, such as common bituminous coal, tan refuse, sawdust, and peat, several of which were now at work and giving wonderfully economic results. By no means the least interesting of these special plants were two sent out last year to West Africa to the order of the British Cotton Growing Association for driving their ginning factories, using waste cotton seed refuse as fuel. The importance of these gas plant developments lay in the fact that till now all the smaller sizes of suction plants had to work on more or less expensive non-bituminous fuel, such as anthracite, coke, or charcoal, whereas now almost any kind of fuel can be used.

---

### Oil Wells: Danger of Fire.

The danger is considerable, and the best way of reducing the damage is to have undrilled zones separating the blocks. There is not much risk from lightning, as there is usually a heavy rain. But the gas creeps a good distance and naked lights should not be used anywhere near wells. The oil itself is not readily inflammable.

---

### Map of the Central and Eastern Provinces of Southern Nigeria.

This map was erroneously attributed in our last number to Capt. Woodroffe. The original map was the work of that officer, but the new map was prepared by Capt. W. H. Beverley, Staff Officer for Intelligence, S.N. Capt. Beverley's work, we observe, has been highly praised in the *Geographical Journal*.

---

### British Standards Committee.

Specifications have now been issued for

Portland Cement (revised Aug., 1910) (No. 12).

Wrought iron for use in railway rolling stock (No. 51).

**Flags.**

It is a curious thing that Union Jacks and Royal Standards are constantly being ordered by Colonial Governments in wrong proportions. There is only one right proportion, and that is 2 by 1—the length double the breadth. There is no reason why the practice should not be uniform throughout the Empire.

---

**Calico Prints.**

In good time a sober, artistic spirit may be developed in East and Central Africa and similar parts, but that day is not yet. In the meantime the most popular designs are made up of railway-engines, motor-cars, aeroplanes, balloons, bursting shells, whisky bottles, and other attractive subjects drawn in heavy lines and startling colours. The natives like this style and the more exuberance the better.

---

**Cotton-growing.**

Enquiries about the best publications on the subject are sometimes received, and the following can be selected:—

“*The Cotton Plant*” (Bulletin No. 33 of the U.S.A. Department of Agriculture; Officer of Experiment Stations).

“*The A.B.C. of Cotton Planting*” (Pamphlet No. 45, issued by the Commissioner of Agriculture for the West Indies).

“*Cotton Cultivation in the British Empire and Egypt*” and “*British Cotton Cultivation*,” by Professor W. Dunstan; Cd. 2,020 (1904) and 3,997 (1908).

## RAILWAY NOTES.

## Central South African Railways.

The report for 1909 brings out (a) the remarkable revival in trade and increased traffics during the second half of the year; (b) resulting benefits to coast Colonies; (c) increase in oversea traffic; (d) the continuously large proportion of the oversea traffic to the Transvaal competitive area via the Eastern route (Delagon Bay), notwithstanding reductions made in rates from other ports; (e) the continued growth of oversea export traffic in grain and coal. The revenue was £5,064,421, the ordinary (*i.e.*, exclusive of renewals) expenditure £1,778,818, leaving a surplus of £2,831,754 after a contribution of £453,849 to the renewals fund. This means a profit of 11 per cent. on the capital, and probably in good time there will be reductions in the charges, which will greatly help to bring about cheaper living in the Transvaal and Orange Free State. But the C.S.A.R. are now combined with the Cape and Natal Railways, and it need hardly be said that the difficulties of these lines tend to retard progress in this direction. The proportion of expenditure has fallen to 35 per cent., a strikingly low figure which can only have been reached by much care and study in amalgamating and organising the departments.

The report states that the average cost of construction, excluding rolling stock, per mile since the war is £4,875. In the case of only 66 miles of line has the cost exceeded £8,000 per mile, but the low average is mainly due to the inclusion of lines built inexpensively for development purposes, to ruling gradients of 1 in 40 with light rails of 45 lbs. to the yard, temporary structures for offices and inexpensive quarters for the staff. The Krugersdorp-Zeerust and Pretoria-Rustenberg lines are typical

of this class, and cost only £2,480 and £2,494 per mile respectively. There can be no question that the policy of constructing lines required for developing purposes to a light standard has been justified by results, and has enabled the construction of more railways than could possibly have been undertaken if the superior standards of the earlier days had been maintained.

The principal agricultural export is maize, and it is to be hoped, in the interests of South Africa and other British possessions which are developing production of this crop, that a market for its sale on a big scale will be established at Southampton.

The employment of white labour on the railways is an important matter on which some interesting remarks are made. There was difficulty in encouraging the increase of white labour, but it was not insurmountable, and there is now every possibility of improving the position of the unskilled labourers at present existing. It may be practical for the Government to force the Central South African Railways Administration and other Government Departments to recruit labour from white sources, existing at present in the country, for to-day thousands of white people are doing work on which a few years ago they would have turned their backs. This evidence of willingness may be looked upon as encouraging and may induce the Government to say that white labour is desirable. But the present conditions are bound sooner or later to lead to unpleasantness. White men have to support a family on wages earned in competition with the natives. As the manner and habit of living of these two races entirely differ, it is urged that the Government should provide suitable dwellings and raise the wages from 3s. 4d. per day (£5 per month) to 4s. per day (£6 per month) of any labourer who for twelve months in succession has completed his duties to the best of his abilities, and if so continued during a further twelve months to a maximum wage of 5s. per day (£7 10s. per month).

The experiments which are being made with various types of motor cars may be watched with advantage by other railways which have occasion for such means of locomotion. The following particulars are given:—

*De Dion Bouton Automotrice.*—The 70 horse-power motor car of the type in use on the Arad Csandi Railways of Hungary, fitted with De Dion Bouton electrogene plant, has arrived, and will be in running order during March, 1910. It has accommodation for thirty-six passengers and a small quantity of luggage, and is capable of hauling a trailer. The current is generated by a dynamo coupled direct to a 6-cylinder petrol engine.

*Stover Rock Island Pattern Car.*—This vehicle, now on order, will have accommodation for twenty-five passengers, and will be

driven direct by a 6-cylinder petrol engine, developing about 60 horse-power.

*Leyland Motor Car.*—This car will have accommodation for forty-two passengers, and can be controlled and driven from either end, thus permitting its use on a section where there is no turntable or triangle. The transmission system is on entirely new lines. The power is furnished by a petrol engine, six cylinders developing 100 b.h.p., and by an ingenious electrical adaptation a variable speed gear is obtained, which adapts itself automatically to suit the speed of the car in relation to the speed of the engine until the speed of the engine and the track wheels approximate one another, when the drive becomes direct and the electrical portion inoperative until automatically brought into use again. The electrical apparatus is used for starting the motor and also assists the motor when starting the car. This variable drive, without loss of power, appears to be particularly well adapted to railway work.

---

#### Uganda, 1909-10.

The total capital expenditure now amounts to £5,414,345. The revenue for the last year was £246,146, an increase of 5·80 per cent. on the previous year, and the net profit was £65,867. This and the preceding results show that the line is progressing very slowly, and the tonnage carried is very small having regard to the area served. The new development of the Union Castle Company should, however, stimulate the export trade, and when sleeping sickness round the lakes is eradicated, as it is hoped will be the case, a substantial improvement may be looked for. The Jinja-Kakindu line will no doubt bring down a good deal of traffic.

Maize is being largely grown and the potentialities are immense.

A large number of distinguished visitors have recently travelled over the line, and vigorous efforts are being made to advertise it. A specimen of our new style of booming official undertakings may be of interest. It is the beginning of the official guide.

“UGANDA RAILWAY.—Never was there such a railway since the world began. In the nature of things it is impossible that there can ever be its like again, for the Uganda Railway is in many respects unsurpassed—wonderful in all. The number of those who have travelled by it is not large—no larger, perhaps, than the number carried by a busy suburban line in a day. But those who have done so never forget. It starts on a windswept island in the blue Indian Ocean, and it ends by the wooded shore

of the largest lake in Africa. In between, it passes through jungle, swamp, and desert; zig-zags across plains where elephants play by day and lions roar by night; corkscrews up the sides of outlandish snow-capped mountains; circles round the base of volcanic, cone-shaped hills; meanders by the "shambas" and cultivated patches of rude inland tribes; strides long-legged athwart treacherous swamps, and ploughs through the darkness of primeval forests, until it emerges, calm but triumphant, from under the flat-topped mimosas by the shelving shore of the shimmering inland sea.

"Anyway, there is it. But it was not built as it is. Originally a large proportion of the line was laid temporarily. That was while profane engineers waited, without patience, for slow-moving manufacturers of steel girders and stays and things. Tired of waiting, they built, whenever practicable, a way round. To-day, traces of the first road abound by the side of the existing track. 'We have not yet built one line to the lake,' the Germans say jestingly, 'but the British have built two.' But the man who paid the piper, not knowing, does not mourn. The Foreign Office did it, and the self-respecting British taxpayer has long since ceased to follow the doings of that Department of State. But Africa has ever favoured the enterprise of the F.O. In spite of itself, the latter was saved from a foolish extravagance by the fertility of resource possessed by this Land of Surprises."

After this the F.O. may breathe again. The sample, "anyway," shows that a Government production need not lack animation or the spirit of optimism. The attractions of the territory are set out with vigour. We observe that a somewhat new (in recent ages) form of sport is recommended:—"Spearing lions in East Africa has for years been a favourite sport of the Masai tribe of natives, and has served a purpose in the development of warriors of the first class. Only in the past year or two has the white man taken to this sensational sport, and, as an American tourist remarked, 'Bull fighting and aeroplaning are nothing compared to it as a "blood ruffler."' The fact that you are unarmed, barring your spear, and depending in a great degree on the nimble feet of a Somali pony is what serves to make ones blood tingle. The excitement of this thrilling sport is destined to attract all travellers in search of a new sensation.'" Perhaps, after all, the average tourist had better stick to a gun.

---

### Lagos Railway.

The Northern Extension of the Lagos Government Railway commences at a point 293 miles from Lagos, and terminates upon

the East bank of the Kaduna River, near Zungeru, at mile 429 $\frac{3}{4}$ , its total length thus being 136 $\frac{3}{4}$  miles.

From Zungeru the line has been extended by the executive staff of the Northern Nigerian Government to Minna, in the Gwarri country, where a juncture with the main line of the Baro-Kano Railway is effected. This latter portion, from Zungeru to Minna, has been termed the Link Line.

About the middle of February, 1909, rail laying from the South reached mile 293, the zero point of the Northern Extension, but owing to the extremely heavy nature of the work, involving formidable rock cuttings, plate-laying up to Jebba, 13 miles further on, was not completed until the following April. The line to Jebba, situated upon the South bank of the River Niger, was opened for public traffic in August, 1909, through communication with the coast at Lagos thus being established for a distance of 306 miles.

In the meantime, earthworks were being pushed on, on the North bank of the Niger, as fast as the limited number of men available would permit, and the banks and cuttings, involving comparatively heavy work, were completed to mile 40 by the end of the year. A considerable amount of earthwork was also completed at the Zungeru end.

The question of the most suitable point for the construction of a railway bridge to cross the River Niger is one which has occupied the attention of the Government and their Consulting Engineers for a considerable number of years.

As far back as 1900, at a time when the Lagos Railway had reached Ibadan, only 123 $\frac{1}{2}$  miles from Lagos, it was recognised that the route of a future possible extension might, and probably would, within reasonable limits of divergence from the general direction, depend largely upon the selection of the site for a bridge, which would present the least difficulties of construction from an engineering point of view, and at the same time involve a minimum capital expenditure in carrying out the work.

With this object in view an expedition was sent out from England about that year under the charge of the late Mr. W. Gee, M.I.C.E., in order to examine the river from Lokoja upwards, and to report upon the possibilities of obtaining a site which would fulfil the necessary conditions. Mr. Gee, after exhaustive investigations, arrived at the conclusion that in Jebba he had found the desired spot, owing to the fact that not only was the river constructed between rocky banks which would afford good foundations, but also that between them an island, some 2,000 feet in width, existed, which would shorten the actual waterway to be spanned by that distance.

The Jebba crossing having been, for these reasons, decided upon as the best possible one to be obtained, it became necessary to establish the possibility or otherwise of connecting Jebba with Ibadan, the intervening 185 miles being, at that time, *terra incognita*, as far as the feasibility of the construction of a line of railway was concerned. A rough reconnaissance survey was therefore carried out with the result that a line with heavy grades and sharp curves was obtained which, however, subsequent investigation has proved to be capable of considerable improvement.

Matters remained *in statu quo* for some years until, in 1906, a reconnaissance survey was sanctioned by Government from Jebba onwards to Zungeru and, the feasibility of this line being also established, sanction was in due course given for the whole scheme of extension, including the construction of the Niger Bridge—that portion over the North Channel having been authorized in 1908, and that over the South Channel in 1909.

Designs for the former having been completed, material for its construction began to arrive in 1908, but, owing to the fact that the whole of this had to be brought a distance of 400 miles up the Niger by S.W. steamers, during the high water months of September, October and November, the delivery was necessarily slow. Moreover, owing to the swiftness with which the river flows through the gorge at the point of crossing, it was necessary to wait until April, 1909, until diving operations could be commenced, and even then work had to be done in a depth of 25 feet of water.

The North Channel Bridge consists of two spans of 100 feet, two spans of 150 feet and three approach arches of 30 feet span each, making a total opening of 590 feet. During 1909 the abutments and piers, with the exception of the middle pier, were got in and completed, the steelwork of the 100 feet spans was erected in position, and the steelwork of the 150 feet spans erected upon the 100 feet spans, ready for launching. The bridge, therefore, was practically completed with the exception of the central pier.

In order to work traffic across the river whilst the South Channel Bridge is being built, a steam ferry has been provided, with a carrying capacity for six loaded wagons. This vessel, named the "Fabius," arrived at Jebba in 1909, having come out from England under her own steam. The necessary slipway approaches are well in hand, and should be ready for work by the time of the North Channel Bridge is completed.

The line across the island between the two bridges involves very heavy rock cuttings, the bulk of which has been completed, and when it is considered that the South Channel Bridge will be

1,300 feet long, and that half its piers will be sunk to a depth, through sand, of 60 feet below the level of the bed of the river, it will be realised that the crossing of the River Niger, albeit 400 miles from its mouth, is a gigantic engineering undertaking, fraught from its inception with the greatest difficulties, not least among which is the deadly climate of Jebba, which has already taken its toll in deaths and invalidings of a large percentage of the European staff engaged upon carrying out the work.

It has been lately most difficult to get labour for the Niger Bridge Division, owing to the rock work and long leads. The Yoruba gangs prefer the work on soft earth and go on ahead to find it, and many dismissals have been necessary. During July the foundations of No. 2 pier were successfully got in, a result which has meant much very hard work.

A considerable amount of work was done in other directions. The deviation works, which meant the reconstruction of the first 130 miles of the railway to bring it up to the standard of the extension, were actively pushed on. The Iddo wharf was extended, and a beginning was made with the Apapa branch railway. Investigations and borings were carried out with the view of carrying the terminus of the railway into Lagos, connecting up with deep-water wharves proposed to be built near Wilmot Point: this extension involves a new bridge across the lagoon between Iddo Island and Lagos, running the railway along the Marina, bridging Five Cowrie Creek, and on to the site of the new wharves. The new foundry was found very serviceable.

The gross revenue for 1909 was £203,558 and the working expenses £131,820: the net revenue therefore was £71,738 or an increase of profit over the previous year of no less than 67 per cent.—a highly satisfactory result when it is remembered that the revenue of the Western Province showed a falling off.

The permanent value of the line seems therefore to be demonstrated. The natives use it in largely increasing numbers, but it is hopeless to expect that the 1st and 2nd class traffic will ever pay commercially, and it may be advisable to abolish the 2nd class, as has been done extensively in this country.

---

### Baro-Kano.

By the end of May the survey was completed, the track had reached mile 212, and shortly afterwards the earthwork was finished to Kano. The work was then stopped during the period of heavy rain, except the bridging in the Kugo Valley, which had to be pushed on in view of next year's track-laying. The total length from Baro to Kano will be 370 miles, including

14½ miles of sidings. The work has been carried on under the greatest difficulties in obtaining food and labour, and heavy expenditure was incurred in filling openings at culverts so as not to stop track-laying and building deviations where it had been intended to carry culverts ahead, and the original estimate will probably be exceeded by at least 5 per cent.

The Baro-Minna section is in very fair running order, but is chiefly ballasted with sand. On the link to Zungeru 18 miles were completed in March, or nearly half the distance.

---

### Lagos Harbour.

It is anticipated that the full completion of the mole works, in association with the dredging operations, will result in the formation of a depth in the entrance to the harbour of not less than 27 feet at high water over a width of channel which will be sufficient for the requirements of the traffic, and that subsequently this depth will be maintained with but little aid from dredging. There is a probability that, before the full completion of the mole works, the progressive effects of the works and the dredging will, in the comparatively near future, create such a depth of water over the bar as will render possible the entrance of the mail steamers. It is proposed to purchase a tug, and the requirements of the future will no doubt be taken into account in fixing its size. By the end of this year the Customs Wharf will have been extended to a length of 648 feet. No doubt, if financial considerations allow, the mole works will be pushed on continuously.

---

### Gold Coast.

The year 1909 was a favourable one. There was a marked activity in the mining industry, with the result that the small agriculturists did well and the spending power of the natives was increased. The revenue was the largest hitherto earned. Rather curiously the output of gold fell, but this is attributed to development work and the erection of new machinery. The net revenue is equal to 6·03 per cent. on the capital account, but it can hardly be expected that this can be kept up as there will be demands for increased facilities, improvements and renewals. Mr. W. E. Smith and the staff are to be congratulated on the success which has attended their work.

The Tarquah-Prestea Railway was extended by July to near the site of Broomassie Station, but the length between the Ankobra Bridge and Prestea awaited the completion of the bridge which was being erected. Rock ballast from the mines is

making ballast of the first class, a great desideratum in West Africa.

The branch platform at Tarquah has been commenced.

The Secretary of State has sanctioned a survey with a view to the construction of a branch line to the Bibiani Gold Fields.

Accra Harbour works—considerable progress has been made with the breakwater extension, a length of 25 feet at low water having been completed by August. On the jetty a length of 110 feet was completed.

Secondee Harbour works—the railway quay extension, the West reclamation wall, and the root wall parapet have been steadily extended, and considerable progress made with the reclamation.

Heavy rains have interfered with the Accra waterworks, but the railway will be pressed on and the transport of materials facilitated.

It has been decided to instal a sand pumping plant with a view to the removal of the sand in the sheltered area in the harbour at Accra. The local difficulties are great, and the extreme fineness of the sand prohibits the use of a small pump hopper dredger, even if there were a sufficient area of shelter available for such a craft. The plant, which is to be made by Messrs. Fleming & Ferguson, Ltd., will consist of two separate pumping engines working in series, the smallest set being portable and carried on trolleys running on rails along the jetty.

In all these public works improvements Sir John Rodger had throughout shown keen interest and unflagging industry, and the progress effected was largely due to him.

---

### Accra-Akwapim.

The abnormal rains of June (over 18 inches) did considerable damage. On the first section the water rose on both sides of the line to within a few inches of rail level—a vast sheet from a quarter to half a mile wide moving slowly down to the lagoon, while at five miles a vast quantity of water, rising above rail level, flowed over the line and washed out earthwork and ballast. At some places a flood of water breached the bank. The damage is materially delaying the completion of the line, and the contractor will have to be allowed an extension of time.

---

### Trinidad.

The proposed works consist of

- (1) The extension of the railway from Tabaquite to Rio Claro, about 15 miles;

- (2) The extension of the railway from San Fernando to Siparia, 16 miles;
- (3) Additional rolling stock for these extensions;
- (4) A connecting link at Princetown, called the Guaracara-Cipero Junction Line;
- (5) The rebuilding and enlargement of Port of Spain Station.

The total cost, including the expenses of raising the loan, has been put at £371,979, but the surveys which have been made are only preliminary, and further examination of the ground is necessary before detailed estimates can be prepared. Arrangements are contemplated for sending out an additional staff for the survey and construction. The work would probably occupy about two years from the date of the acquisition of the land.

---

### Cyprus.

The returns for 1909-10 confirm the view previously expressed in these pages that the railway is in the wrong place. The proper line of trade is not with Syria, but with Egypt, and for one steamer that calls at Famagusta there are fifty at Larnaca. The receipts show a falling off of 15·3 per cent. on those of the previous year.

---

### The A.B.C. Coupler.

Enquiries have been made as to this coupler, which is being used on some Indian railways. It has considerable advantages, the coupling being automatic and reducing the distance between vehicles, but it is rather complicated and requires careful men in charge of the shunting. The draw and buffing springs are of steel and the release and engagement of the locking bar is controlled by two more steel springs of a smaller size; this part of the apparatus would have to be kept scrupulously clean from dust and dirt.

The cost of converting a broad gauge wagon into one with A.B.C. couplers is about £20.

---

### Hard Water in Boilers.

Report No. 9 on the question of Improvements in Locomotive Boilers, presented to the International Railway Congress, indicates the methods adopted by the railways which have only hard water available in order to prevent damage to their boilers. They have tried the frequent washing out of boilers, and the purification of the water. The chemical processes of purification have

proved that it is necessary to avoid the presence of an excess of soda in the purified water; and consequently many of the railways only effect a partial purification of the water by means of soda. At three of the stations on the Central Asia line, the very hard water is purified by distillation. Purification of the water by means of zinc, barium salts, Campeachy wood, petroleum residues, etc., has only been tried in a few exceptional cases. Boilers are washed out, either with hot or with cold water, after running 330 to 530 miles on some lines where only hard water is available. Blowing off the boilers under pressure is not a general practice. Hard water has a great influence on the corrosion of the boilers and on the regularity of the train service. The residues left on evaporating hard water which are in the form of scale, attack the iron walls of the boilers immediately, probably by a chemical action; and on the other hand the walls made of copper, which are subjected to the immediate action of the fuel, have a greater tendency to burn away in consequence of the reduced conductivity produced by the adherent scale. These two cases result in damage of different kinds, namely, in the case of iron walls—corrosion, cracks and grooving, rarely fissures; in the case of copper, on the other hand, in fissures, cracks and in burning away, according to the thickness. The places where damage occurs are those which are subjected to repeated bending from the periodical heating and cooling of points where scale can collect without difficulty; for instance, the lower part of the barrel, that of the fire-box and the crown of the latter. As protection against such damage, the following methods are mentioned: stiffening the walls of the boiler so as to reduce the amplitude of the flexure when heating up; the use of mud pockets for the residues obtained by the evaporation; as well as a design of boiler which makes it easier to scrape and wash out the scale, and prevents the deposit of the latter.

When lime and caustic soda are used to soften water the proportions used vary according to the quality of the water. A tank should be filled with water and lime added and the contents well stirred; the resulting lime water is then run into the softening tank. Another small tank is filled with water and caustic soda, and this solution is also run into the softening tank, which should be well stirred and allowed to settle for about 20 hours.

## MEDICAL NOTES.

In discussing the functions of the Press at the official luncheon given by the Government to the Institute of Journalists on September 10th, Colonel Seely emphasized the importance of research in the sphere of tropical medicine and commended it to the press of all countries as a cause pre-eminently deserving their support and encouragement. There is no sphere of scientific work in which the benefit accruing to mankind from research is more immediately obvious, and the advance which has been made in the past ten or fifteen years is as great a triumph of man over the forces of nature as any which has been recorded in our time, not excepting the more sensational, but probably less beneficial, "conquest of the air."

Even putting aside humanitarian considerations, the economic importance of medical research to a tropical or sub-tropical country cannot be over-estimated. It is well illustrated by the following extract from the report of the Egyptian Department of Public Health for 1909 :—

"There are now probably few countries in the world that offer so attractive and untouched a field of scientific investigation as does Egypt. In many parts of the country the population is not sufficient to work to the best advantage the resources of the soil, and yet the most valuable economic asset of labour is decimated by infectious diseases the prevention of which has yet to be a matter of study; the initial causative factors of trachoma (the origin of the greater part of the eye disease of the country) are still unidentified; the investigation of pellagra, which causes 20 per cent. of the lunacy and much more of the physical disability of the country, is only being begun; the penetration of the mysteries connected with the methods of infection of a large proportion of the people with anchylostomiasis and bilharziosis, and parts of the life-histories of the parasites concerned, has still to be completed; the methods of communication of typhus and relapsing fever have by no means yielded up their

secret; the distribution of malaria has not yet been defined, and the factors which are still wanting to determine its actual presence under apparent conditions of potential existence are as yet undiscovered; the diseases of cattle and domestic animals, of camels and horses, afford a gigantic field for investigation which would readily repay the Government for such financial sacrifice as is necessary to place a work of this kind on a sound footing; finally, the rôle of insects and the lower scale of animal life in the propagation of disease among men, animals and crops is still another field that offers promising results. (In connection with this point it is satisfactory to be able to state that relations have been established with the Entomological Committee of the Colonial Office—presided over by Lord Cromer—and it is hoped that mutual advantage may accrue.)

It is clear, therefore, that there is no lack of useful experimental and investigational work to be done, but the work awaits a suitable series of laboratories and an adequate staff to undertake it. For this purpose money must be spent, and spent freely; but it is certain that it will, in the future, be returned to the Government many times over, for as nothing is more wasteful than the false economy of unscientific methods, so no expenditure is more surely and safely remunerative than that which follows where honest enquiry and the quest of exact knowledge direct."

---

### Tuberculosis.

This disease is directly responsible for one-seventh of the mortality of the civilised world and indirectly for an incalculable amount of waste. The old idea was that it was chiefly a disease of cold climates, but there has been in recent years a great increase of it in hot countries, and it is now clear that the greater prevalence of it in the former was due, not to the cold, but to greater overcrowding. At present, on the whole, it is being greatly reduced in European countries, but greatly on the increase in other places where the population is going up at a rate in advance of sanitary precautions. Thus in Colombo the deaths from phthisis have gone up from 25.66 in 1899 to 44.05 in 1909 per 10,000 inhabitants, and acute cases commonly called "galloping consumption" are more common there than in England; in fact the disease is more rapid and hopeless than it is here. With both man and beast the problem is one of fresh air. Jersey cattle in their native island, staked out at pastures all the year round, are exempt, whereas the housed Jerseys of England and America suffer severely. The root of the evil can only be attacked by improving the social conditions and educating the public. As regards treatment of cases, a Ceylon Commission advocates compul-

sory notification, the establishment of sanatoria, and the following prophylactic measures :—

(a) The prohibition of expectoration in public places, such as offices, and public conveyances, &c.

(b) The inspection of schools and children in schools.

(c) The inspection of factories.

(d) Roads and streets should not be swept without being first watered, as otherwise disease may be disseminated by the dust from the roads being carried into the air in large quantities.

(e) The prohibition of persons obviously suffering from phthisis from working in factories and offices without proper precautions being taken to prevent the spread of the disease.

(f) The discontinuance of the use of coir rugs as spittoons.

(g) The provision of special places in parks where poor people suffering from the disease can receive open air treatment during the day.

---

**Sleeping Sickness Bureau.** BULLETINS NOS. 19 AND 20, VOL. 2.  
(*Royal Society*).

Experiments made prove that cattle and antelope living in the fly-area may act as a reservoir, and so keep up the infectivity for an indefinite period. These observations, however, do not go far, and many smaller animals, including birds, will have to be tried before it can be concluded that they do not harbour the pest.

The bulletin records the news of the sickness in various parts of Africa. There is no better prospect of a medicinal cure.

---

Volume IV., No. 1, of *Annals of Tropical Medicine and Parasitology* issued by the Liverpool School of Tropical Medicine is mainly taken up by reports on the Amazon Yellow Fever Expedition (1905-9) by Dr. H. Wolferstan Thomas. The opening words of the introduction bear witness to the perilous nature of the work so readily undertaken by our medical investigators. "The Liverpool School of Tropical Medicine despatched the fifteenth expedition comprising Dr. Anton Breiul and the writer to Manaos in April, 1905, in order to investigate yellow fever and the diseases of the Amazon State. This expedition was the second sent to the Amazon region, the first one, in 1900, having been stationed in Pará. Shortly after its arrival in Manaos, both members were attacked by yellow fever and subsequent complications in the case of Dr. Breiul unfortunately necessitated his return to Europe, and thus his valuable services were lost to the expedition." Dr. Thomas, who had to perform his work single-handed returned to England in February, 1909. A new expedition has now been organized. A photograph of the tablet erected to commemorate Dr. Walter Myers, who died in 1901 of yellow fever contracted on

the Liverpool School's previous expedition is published, together with a portrait of Dr. Myers at work with the microscope, as a frontispiece.

---

A number of experiments were carried out for the purpose of obtaining a cheap and efficient preparation for destroying mosquito larvæ. Crude petroleum oil was frequently too viscid to have a spreading power of the highest efficiency. When mixed with crude carbolic acid, however, its spreading powers were increased.

Much of the crude carbolic acid supplied had been found upon analysis to consist chiefly of inert neutral oils with a small proportion, 5 per cent. to 10 per cent., of tar acids, and as this crude acid was used extensively as a disinfectant, experiments were conducted for the purpose of utilising if possible this crude carbolic acid as a disinfectant and larvacide. It was found that crude carbolic acid, having a specific gravity not greater than 0.96 or 0.97 and containing about 20 per cent. of phenols or tar acids, when made into a soap with common resin and an alkali yielded a product which was an ideal larvacide, having excellent diffusing and toxic powers, and at the same time it was a very efficient germicide. It diffused perfectly with water, forming a milky emulsion very destructive to mosquito larvæ, and having a germicidal value of, or greater than, that of pure carbolic acid, or a Rideal-Walker co-efficient of one to two. In this way a very valuable larvacide and disinfectant, miscible with water, was produced from a very inferior disinfectant.

---

Experiments were made to determine the proper mesh of wire screening, a matter on which there has been much official correspondence. A No. 16 mesh (16 holes to the inch) was found sufficient to keep out Anophelines though not the smaller species.

The destruction of noxious insects by culture has been extended to locusts. There is a fungus which grows on their living tissues and which can be artificially cultivated and used for destructive purposes. There is a well-known and closely related example which is parasitic on the common house fly and known as *Empusa muscæ*. Everyone is familiar with the dead fly stuck to the window panes and a white halo round its body—the shroud which has also been the cause of its death. The tubes or hyphæ of the fungus are inside the body of the locust, and when they have used up all the nutrient material in the tissues, they project at the surface and produce pear-shaped conidia. When the conidia are ripe they are shot out as if from a pop-gun, and if they strike the body of another locust they may infect it, and in this way the disease is spread. These conidia are produced in countless myriads and scattered, so that the fungus is not only widely distributed, but also rapidly reproduced.

---

**Rat Virus.**

One of the Medical Officers of St. Lucia reports that the result of experiments into rat viruses is that those sold commercially are of little value, far less value in fact than the inorganic poison such as phosphorus and strychnine. Yet, if a virus, such as Danysz's is raised in virulence by repeated passages through the peritoneal cavity of rats and grown on rat serum agar it appears to be of considerable value. In experimenting with these poisons he always supplied the rats with other food besides that which was poisoned, so as to see whether they avoided the poison or not. The advantage of viruses is that they are practically non-pathogenic to fowls, cats, dogs, mongoose, etc.

In Jamaica it was found that a bread bait saturated with milk cultures of virus grown at the Laboratory possessed marked virulence.

---

**Mosquitoes and Malaria.**

The same report gives the following results of an extended search :—

(1.) That their breeding places contain surface food, suspended by grasses and other plants growing in the water, or lowly organised plant life such as algæ growing on the surface, or floating and decomposing rubbish.

(2.) That in more than ninety-five per cent. of cases their breeding ground is non-permanent. That the pools tend to last during and for a short time after the rains, and they are usually shallow.

(3.) They are rarely or never pools in an open piece of land unprotected by rocks, bush, or other vegetation, and that tend to be continually wind swept.

(4.) They are never pools in which canes or tall reeds and bamboos grow, which exclude the light.

(5.) The larvæ are not found in pools which possess a continuous current of water, or if they occur in connection with these pools it is in those parts that are protected by vegetation from the current.

(6.) The Anopheline larvæ are not found in close association with their natural enemies, nor in any situation that is easily reached by their natural enemies.

The use of the "Millions" fish for the extirpation of larvæ is strongly recommended, and as difficulties have been experienced in exporting these the following observations may be useful to other medical authorities.

(1.) I obtained about twenty fish from the swamps of Gros-Islet and placed them in two old spirit barrels, which had previously been soaked in tanks for two months. In these barrels I have now bred many thousands, which have been variously distributed.

(2.) At first the fish would not live in iron tanks, but by mixing a little water from rusty tanks with a large quantity of rain water and gradually increasing the percentage of the rusty tank water, I obtained fish which would live and multiply in iron tanks.

(3.) In the same way I succeeded in immunizing fish to darkness.

(4.) By gradually adding water from brackish swamps they are immunized to brackish water.

(5.) I have had great difficulty in getting fish to live in and show signs of multiplying in water at and above 100° Fah., but I have now succeeded, and the difficulty I believe was entirely due to the dark incubator with which I was obliged to work, layers of fungi quickly appearing on the surface of the water, and their food material quickly decomposing. Continually changing the water and adding fresh food and allowing the sunlight to play upon the water each day, has enabled me to get fish to flourish at these higher temperatures. I have had difficulties with the lower temperatures, but the experiments conclusively show that these fish can be gradually immunized to temperatures ranging from 101·5° Fah. and 55° Fah. and there appears to me no reason why higher and lower temperatures should not be employed, if a considerable period of time is used to obtain the immunity.

(6.) I once placed six fish in a kerosene tin containing numerous mosquito larvæ, the next day all the larvæ had disappeared. I did not change the water, at the end of three weeks there were twenty-three individuals. Shortly after this some of them began to die. They had thus lived and multiplied in two to three gallons of stagnant unchanged water.

(7.) It is almost impossible to state their exact power of destroying larvæ and pupæ in figures, as both larvæ and fish vary so greatly in size, but this power is enormous, for I find two or three fish will soon clear a 10,000 gallon tank and keep it free of larvæ.

---

### Northern Nigeria.

The European death rate in 1909 was 23·89 per 1,000, or, excluding deaths from accidents, 16·5. This seems satisfactory, but it must be remembered in comparing with ordinary statistics that the Europeans are mostly picked men. The invaliding rate was 118·7 for officials and 141·5 for non-officials, a difference which shows that the more

liberal arrangements made for the former have a good effect. Seven cases of sleeping sickness were met with, and there is no doubt that the disease has existed for many years in the country. Clearing the undergrowth and thinning the larger trees was found to give gratifying results in diminishing the number of tsetse flies, and this policy might be followed in other places in the neighbourhood of water.

Arrangements have been made by the Colonial Office for short courses on entomology to be given at the two Schools of Tropical Medicine, at Oxford, Cambridge, Edinburgh, and Dublin, for the benefit of officers in the African Colonies and Protectorates when home on leave. Advantage has already been taken of this in a number of cases, for during the present summer the following numbers have taken, or are taking, courses in entomology :—Officers from the Gold Coast, 7 ; from Sierra Leone, 2 ; from Northern Nigeria, 1 ; from Southern Nigeria, 8 ; from the East Africa Protectorate, 3 ; from Uganda, 1 ; from Nyasaland, 2 ; making a total of 24. Twenty-two other officers have intimated their desire to take the course in the near future.

## COLONIAL STAMPS.

BAHAMAS.—The 1d. Queen's Staircase stamp will shortly be supplied for the first time on multiple watermarked paper.

BARBADOS.—2d. and 1s. stamps in the new colours (the latter a new value) have been supplied.

EAST AFRICA PROTECTORATE.—The 6 cents. stamps have been printed from a single plate, but there is no perceptible alteration in their appearance.

FEDERATED MALAY STATES.—The new Trengganu stamps have been supplied and the colours of the series of values mentioned in our July number correspond with the  $\frac{1}{2}$ d., 1d.,  $1\frac{1}{2}$ d., 2d.,  $2\frac{1}{2}$ d., 3d., 6d., 1s. and 2s. 6d. values in the colour scheme respectively, doubly fugitive ink and surfaced paper being used for values over 10 cents.

GILBERT AND ELLICE ISLANDS PROTECTORATE.—Fiji stamps of  $\frac{1}{2}$ d., 1d., 2d.,  $2\frac{1}{2}$ d., 5d., 6d. and 1s. values have been surcharged as above for use in that Protectorate. The surcharge in the case of the 1s. stamps is for the sake of distinctness in red, the other values in black.

GOLD COAST 2s. stamps have been despatched in the new colours, but in singly fugitive ink and unsurfaced paper.

HONG KONG 1 cent. stamps have been printed in the new colour for the  $\frac{1}{4}$ d. value.

JAMAICA  $2\frac{1}{2}$ d., 4d., 1s. and 2s. stamps have been supplied for the first time in the new colours, the last three values being of the Queen's Head design.

LEEWARD ISLANDS 5s. stamps in the new colours have been despatched to the Virgin Islands, and 3d. stamps to Antigua.

MALTA.—The colour of the latest printing of the  $\frac{1}{2}$ d. stamp has been slightly altered to correspond with that chosen for this value on the colour scheme.

NEW HEBRIDES.—An issue of Fiji stamps surcharged "New Hebrides Condominium" has been made. The following are the values of the stamps:— $\frac{1}{2}$ d., 1d., 2d.,  $2\frac{1}{2}$ ., 5d., 6d. and 1s., and the colour of the surcharge corresponds with the Gilbert and Ellice Protectorate Series.

ST. VINCENT  $\frac{1}{2}$ d. and  $2\frac{1}{2}$ d. stamps of the new design have made their first appearance.

SOUTHERN NIGERIA 1d. stamps have been supplied printed from a 240 set plate at one operation, but the design is the same as before.

STRAITS SETTLEMENTS.—1 dollar stamps in the new colours, *i.e.*, red and black on blue paper, and two new values, *i.e.*, 21 and 45 cents., have been supplied. The colours of the two last named stamps are those appropriated to the 6d. and 1s. sterling values on the new colour scheme.

---

The first of the Crown Colonies and Protectorates to print advertisements on the interleaves of stamp books is Southern Nigeria. The advertisements are printed in red on one side only of the wax paper.

**RECENT TRANSFERS AND PROMOTIONS  
MADE BY THE SECRETARY OF STATE.**

Captain H. DU B. O'NEILL (Assistant Political Officer, Somaliland),  
Assistant District Commissioner, Uganda.

Mr. R. C. CORFIELD (Assistant Political Officer, Somaliland),  
Assistant Resident, Northern Nigeria.

Lieutenant G. L. UNIACKE (Captain, Northern Nigeria Regiment,  
West African Frontier Force), Assistant Resident, Northern  
Nigeria.

Mr. L. C. DALTON (Assistant Resident Magistrate, Orange River  
Colony), Registrar of the Supreme Court, British Guiana.

Mr. G. HAZLERIGG (late District Commissioner, Gold Coast),  
Registrar of the Supreme Court, Ceylon.

Dr. L. H. BOOTH (Assistant Surgeon, New Providence Asylum,  
Bahamas), Medical Officer, West African Medical Staff.

Mr. D. R. A. BETTINGTON (Inspector of Police, Sierra Leone), Deputy  
Commissioner of Police, Gold Coast.

Mr. P. E. BRADNEY (Inspector of Police, East Africa Protectorate),  
District Superintendent of Police, Northern Nigeria.

Mr. G. WATERS (South African Constabulary), Assistant Inspector  
of Police, Uganda.

Mr. J. SOMERVILLE (Postmaster-General, Northern Nigeria), Post-  
master-General, Gold Coast.

- MR. H. M. WOOLLEY** (Deputy Postmaster-General, Northern Nigeria), Postmaster-General, Northern Nigeria.
- MR. G. C. ANDERSON** (First Grade Customs' and Excise Officer, British Honduras), Assistant Receiver-General, Gambia.
- MR. W. F. O'TOOLE** (Second Division Commissioner, Bahamas), Second Class Supervisor of Customs, Gold Coast.
- MR. J. F. H. GRANT** (Customs' Officer, Barbados), Second Class Supervisor of Customs, Gold Coast.
- MR. C. S. CRAVEN** (District Engineer, P.W.D., Gold Coast), Resident Engineer, Gold Coast Water Works.

**OFFICIALS ON LEAVE OF ABSENCE  
IN THIS COUNTRY WITH DATE OF  
EXPIRATION OF LEAVE.**

—

This List is compiled from the Leave Certificates sent to the Crown Agents for the Colonies. The Editors will be glad to receive notice of any other cases of Colonial Officials on Long Leave.

EDITORIAL NOTES.

It is a happy feature of the Royal visit to South Africa that Canada, Australia and New Zealand sent representatives to meet the Duke of Connaught, and to take part in the proceedings. Any occasion which tends to bring the great Colonies into contact with one another strengthens the union of the Empire, and the visiting delegates cannot fail to take home with them, and to be instrumental in spreading, a larger conception of the Empire and an appreciation of the common spirit which animates it. Probably in the near future there will be developments of direct trade between the dominions and the Crown Colonies which will give them a greater national interest in one another. The South African war led to a new trade between South Africa and Australia, and though this was accompanied by some political friction for a time over the labour question, the communication is sure to grow. The trade with Canada is also a promising field. The cost of freight is always a determining factor in such cases, and what is wanted, especially in the case of South Africa, is an increase of exports which will encourage the growth of shipping facilities. The excellent recent railway results in South Africa are a good indication of agricultural improvements, which open up a prospect of this result, and the Government is fully alive to the importance of the matter.

The referendum having recently become, in a somewhat unexpected manner, a live issue in British politics, attention is likely to be concentrated upon the use of this device by some of the self-governing dominions. The Commonwealth Parliament has recently passed two Bills for the amendment of the Constitution, both of which must pass the ordeal of the referendum before they can become law. But we doubt whether either friend or foe of the institution will be able to draw from this particular Australian instance any argument genuinely applicable to home politics. The real *raison d'être* of a referendum in Australia is to be found in the federal nature of the constitution of the Commonwealth. A federal constitution, as Mr. Bryce and others have pointed out, has about it much of the nature of a treaty, and an alteration of its terms may not unreasonably seem to require a reference to the original contracting parties. In the case of the United States of America, this doctrine has been pushed so far that an alteration of the constitution has proved to be practically impossible except under the strain of revolution or civil war. As might be expected, in so typically British a community as Australia, theory has not been pushed to such an extreme. But it must be remembered that the Commonwealth Constitution had its origin in a referendum, and it is only natural that recourse to a similar expedient should be necessary in order to alter it. Of the two Bills to be submitted to this process, one gives the Commonwealth control over all matters of commerce, trade and industry throughout Australia; the other empowers Parliament to nationalise industries which it may see fit to regard as monopolies. The origin of both is to be sought in the somewhat short-sighted policy of some of the States in fighting too hard for their own hands, and the general anticipation appears to be that both will be accepted by a majority of the people of Australia. Decisions of the High Court have in effect defeated Commonwealth legislation with regard to the settlement of labour disputes and the establishment of the so-called "New Protection," and Mr. Fisher has chosen a direct and drastic method of achieving results which Mr. Deakin failed to achieve by persuasion and conciliation.

---

The idea of an "all-red" cable has been recently brought up again in connection with a rumour that all the existing trans-Atlantic lines will be pooled in an American combine. It would never be safe to put any limit to the enterprise of our American cousins, but at any rate they cannot buy up the Atlantic Ocean; and if and when the pool is formed and managed in any way which would be prejudicial to British interests, it would be no difficult matter to lay other cables if this should seem advisable. It is not very likely, in view of the fact that the opportunities of competition cannot be limited, that the pool, if it became a fact, would put up

Atlantic rates. The object would probably be to save administrative expenses, and to secure the full advantages of combination between all the cables and all the land lines. Nor is a new line wanted for strategic purposes, as was urged in favour of the Pacific cable. The Empire has got both ends of the route within its lines. But both the Canadian and Australian Governments appear to be in favour of a State-owned trans-Atlantic cable, with the view of reducing rates. The comparatively heavy charge over this section for Press rates stands in the way of really low charges. Business of this kind pays to—

Atlantic ...	...	...	...	5d. per word.
Canada ...	...	...	...	1d. „
Pacific ...	...	...	...	2d. „
Australia...	...	...	...	1d. „

In addition to this the Atlantic companies refuse to accept messages from the Continent for the Pacific cable on the same terms as those from the United Kingdom. So the State line gets none of this business.

The difficulty would, of course, be the interference with private enterprise in a sphere where there is no lack of accommodation. An eminent electrician has recommended the adoption of a route via Iceland and Greenland, and, owing to the short spans, this line would give a rapid service and carry a great volume of business; but it would not be “all-red,” and the administrative difficulties would be considerable. Probably a better route would be from the North of Ireland to Newfoundland. The capital cost would be about the same.

---

The South African Parliament has a long programme before it for its first session. To begin with, it will enjoy the unusual privilege, already accorded by circumstances to the Imperial Parliament, of passing two Budgets during a single session. In order that the sittings of Parliament may be held during the summer months at Capetown, the financial year is in future to end on March 31st, and it will be necessary to make financial provision for the whole period from June 1st, 1910, to March 31st, 1912. The Union Government was given special authority by the South Africa Act to incur expenditure for the earlier part of this period without Parliamentary authority, but the Union Parliament is to be invited to consider the question of finance for the whole period of twenty-two months. General Botha in his statement foreshadowed a large number of measures rendered necessary by the Union of the four former colonies. It will be necessary to provide for the consolidation of various departments of the public service hitherto carried on separately, and to establish uniformity of law with regard to

marriages, and many other important questions which clearly do not admit of diversity within the Union. The first steps will be taken towards the establishment of uniformity of taxation, but it is recognised that the completion of this task must be a work of time. It would seem probable that the work of the first session of Parliament will not be of a highly contentious nature. There is so much purely constructive work to be undertaken that there is likely to be a general agreement to allow the more controversial questions to rest until a time of greater leisure. It is all for the good of South Africa that a period of co-operation between opposing parties appear to be inevitable.

---

Our ably-written South African contemporary *The State* devotes the first article in its November issue to the question of the payment to members of the Transvaal Legislature of the full sum of £300 each in respect of their last session, which, it will be remembered, formed the subject of discussion in both Houses of the British Parliament in the summer. It is important that the question at issue should not be misunderstood. The propriety of the action of the Transvaal Assembly in voting this payment to themselves is a matter for South Africa to decide. The Home Government was not in any way called upon to express an opinion, and the spokesmen of the Government in both Houses of Parliament carefully refrained from doing so. But our contemporary charges the Home Government with having instructed the Acting Governor to exercise a discretionary power vested in him in a manner which the Courts had declared to be illegal. In reply we can only point out that so high a legal authority as the present Attorney-General was clearly of opinion that the Home Government were bound to act as they did. The contention of *The State* is, in effect, that even when a statute assigns a power expressly to the "Governor-in-Council," the Governor retains a personal responsibility for its exercise. If this contention be correct, it is not easy to discover a motive or a justification for the distinction made in every constitution between the Governor and the Governor-in-Council. Under a system of responsible government, even when a power is assigned to "the Governor," he is expected to consult his constitution of advisers as to its exercise, but he cannot divest himself of a certain degree of personal responsibility. In the last resort he may decline to accept the advice of his ministers, and dismiss them or accept their responsibility. But when the power is expressly given to the "Governor-in-Council," it is for ministers to decide whether and how it shall be exercised. We wonder whether our contemporary would seek to attach to the King personal responsibility for the many and various powers exercised by "His Majesty in Council!"

---

In connection with the scheme for a London Memorial to the late King, Lord Northcote has addressed to the Lord Mayor a powerful appeal in favour of the establishment of a Research Fund for the furtherance of scientific and practical work in connection with Tropical Medicine. Other schemes are under consideration by the Mansion House Committee, and the amount of money which will be available is as yet uncertain. But Lord Northcote's proposal has behind it such a weight both of argument and of authority that we are confident that it will be carried into effect, whether as part of the King's Memorial, or as an independent scheme. Lord Crewe, Mr. Chamberlain, Lord Elgin, Lord Kitchener, and a host of others have lent their names in its support, and it makes so direct an appeal to a variety of worthy motives that it can hardly fail to arouse a ready response. To the humanitarian it offers an opportunity of effecting an immense abatement of the sum-total of human suffering; to the man of affairs, a means of opening the way for civilization and enterprise in tropical countries hitherto half-closed by the menace of disease; to the scientist, a further stage in the triumph of human intellect over the obstacles set in its way by nature. The amount of work which has already been accomplished with but slender financial resources is a testimony to the splendid devotion both of doctors and of administrators in our tropical possessions, and Great Britain is generally recognized as standing in the forefront of this branch of research. But the time has come for more systematic and continuous effort promoted by adequate funds, and we feel sure that the occasion will not be allowed to pass unheeded.

---

The recent strike on the French railways was followed with close interest in other countries. Trouble on the French lines causes a disturbance of the international traffic of all Southern and Central Europe, and also imperils or retards communication with the East. But the interest with which developments were watched was due less to immediate consideration of practical convenience than to the consciousness that every country is faced with the possibility of an outbreak at some time or another of similar difficulties. The French Government on this occasion took an extremely strong line, and by the issue of a mobilization order brought a large number of the strikers within the scope of military law. Their policy was successful, and a speedy collapse of the strike was the result. But the real cause of the collapse is probably to be sought in the resentment of the general public against the violent methods of the strikers, and the inconveniences and dangers resulting from them, and in the reluctance with which many of the men themselves had yielded to the order to strike. A critical situation may call for desperate remedies;

but it is very hard to defend, as a general method of preventing strikes, a measure which compels the employees of a private company to continue to work for their employers on terms unacceptable to themselves, under penalty of being treated as mutineers. The incident brings out the difficulties inseparable from the private ownership of so essentially national a service as that of the railways. A private quarrel which imperils the continuity of the service amounts to a national emergency calling for Government interference. But interference which takes the form of enforcing, even temporarily, the claims of one side, is contrary to the principle of impartiality which is expected to regulate Government action in respect of private quarrels. M. Briand apparently intends to introduce drastic legislation to render strikes on the railways impossible in future. If he succeeds, it will be a curious reversal of the recent action of the French Chamber in recognising the right to strike, even on the State-owned lines. M. Millerand has parted company with his former chief, and is understood to favour recourse to legislation on the lines of the Canadian "Lemieux Act," to which a good deal of attention has recently been directed in France. The Act appears to continue to give satisfaction in Canada, and we have on previous occasions suggested that it supplies a precedent which is likely to be more useful to the United Kingdom than the compulsory arbitration laws of Australia and New Zealand. In this connection, we may note that the Executive of the Canadian Trades and Labour Congress, in their last Annual Report, expressed the opinion that the organized workers of Canada were almost unanimously opposed to compulsory arbitration, and were of opinion that it would lead to strife and industrial disturbance; and that the Canadian Federation of Labour, at their Annual Convention, passed a resolution to the effect that the Lemieux Act has rendered great services to the country.

---

The negotiations in connection with the West Indian mail service have failed to bring about an agreement. This was not due to any lack of expressions of opinion in the colonies concerned in favour of the service. A meeting of delegates in Barbados in November expressed in stirring terms its conclusion that the discontinuance of the service would be highly detrimental. In quite a number of meetings in other colonies various bodies have expressed themselves to the same effect. But when it came to the prosaic business of paying, only one colony came forward. Trinidad was willing, if made the port of transshipment, to give a subsidy of £15,000 a year, the others nothing. This is a matter for the colonies to decide, and if they do not think that the service is worth paying for there is nothing more to be said: but it is difficult to reconcile this result with

the numerous protests against the discontinuance. A good many countries have to pay to secure a regular mail service. The case goes to show the weakness of an unfederated group in dealing with a subject for which combined action is necessary.

---

Portugal, with a population of about 5,000,000, still rules territory in Asia and Africa of some 2,300,000 square kilometres and a population of 20,000,000. Their West African administration has exposed itself to charges of which a good deal has been heard lately, but in criticising it it is as well for us to bear in mind that at no very remote period the English treatment of slaves was harsher than the Portuguese or the Spanish. Certainly the colour bar has counted for less with the Portuguese than with any other European race, and on the whole it may fairly be said that they were the first colonisers who cultivated the habit of sympathetic understanding of the natives. At the present day our most important point of contact with the Portuguese possessions is at Delagoa Bay, 52 miles from the Transvaal border, and connected by railway with Pretoria. The importance of this line is being rapidly augmented by the development of Rhodesia, and no doubt before long another direct line will be laid from the East Rand, bringing it within eleven hours of the sea. This work would open up Swaziland and create a great new agricultural trade. There is no reason to doubt that Portugal will cordially help these developments, and the suggestions that have been made in some quarters for endeavouring to acquire Delagoa Bay are, to say the least, inopportune.

---

The unity of nations is being more and more promoted by commerce, and, though no doubt rumours of wars and political complications give the most exciting and alluring matter in the columns of newspapers, it is as well to note that an immense amount of work is being quietly and efficiently done, by both public and private organisations, to deal with special interests internationally. Undoubtedly the old walls between nation and nation are largely breaking down. We are, of course, still far from the stage when frontiers will be mere administrative particulars, but the tendency is that way. All markets are now more or less international, and many products have a world-wide market. The improvements in communications are constantly bringing the world into closer relation, and a new process or invention affects the population from pole to pole. Comparative studies therefore become increasingly necessary. The ultimate object of these is mainly to prevent waste, by bringing the consumption and production of the world as far as possible into harmony. The attempt to do this with the most important and

universal of all industries—agriculture—is being made by the International Agricultural Institute at Rome. The method is to collect reliable, rapid and complete information on production from all quarters, so that, the facts being ascertained, prices will not be at the mercy of false alarms or deliberate manipulations, but will correspond to the real ratio between available supply and effective demand. It is not to be expected that this can be done at once, but very strong international support has been given to the movement. Our possessions are by no means backward in agricultural research, and the number of agricultural journals is very considerable. We must, however, yield place in this matter to Germany: in Prussia alone there are about 40 agricultural stations, and an international bibliography of agriculture has been formed. There is in fact a plethora of matter, and the Institute at Rome will undertake the valuable work of bringing the materials together.

---

A remarkable instance of advanced social work is afforded by the Australian departmental conference which was appointed to consider uniform standards for foods and drugs. The object was to fix specifications for the preparation of these articles, and all familiar food-stuffs were dealt with in this way. The primary object is to protect the health of the public, and the ingenious gentlemen who in less watchful latitudes impose on a credulous public cheap preparations under the name of infants' foods, invalids' foods, renovated butter, and mysterious essences and beverages, would find themselves checkmated by the definite requirements specified. In this country we are satisfied at present with a very partial provision against injurious adulteration, and an occasional police-court prosecution serves to reveal the curiosities of manufacture and the deceitfulness of trade descriptions. It is a big step forward to specify, not merely what a food or drug should not contain, but also what it should. But it is undeniably consistent and logical. In Australia the policy of dealing thoroughly with the matter has also been influenced by the desire to prevent imported articles from competing unfairly with the products of the country, and it was of course plain that if specific requirements were on this account applied to imports they should be extended to domestic processes. The result is a long list of specifications, on the following lines:

(1.) Standards for all commonly used manufactured or prepared food stuffs, such as condensed and concentrated milk, butter, renovated butter, margarine, cheeses (various), infants' foods, invalids' foods, manufactured meat, meat extracts, coffee mixtures, cocoa products, jams, jellies, preserved fruits and vegetables, glucose products, confectionery, essences, beverages (alcoholic and other),

cereal foods, cream of tartar, baking powder, vinegar, edible oils, sauces and pickles, spices.

(2.) Standards for drugs.

(3.) The prohibition, limitation, and conditioning of the use of preservative substances.

(4.) The prohibition, limitation, and conditioning of the use of added or foreign colouring substances.

(5.) The principle of explicit and conspicuous declaration of the presence, nature, and amount of any allowed preservative substance.

(6.) The principle of explicit declaration of the presence and nature of any added or foreign colouring matter.

(7.) The prescribing of uniform formulæ in descriptive labelling—for example, the labelling of condensed milk, to show to what extent it may be diluted to yield a milk of standard composition.

---

Mr. C. W. C. Parr, who was recently appointed by the High Commissioner for the Federated Malay States to enquire into the condition of indentured labour, has written two interesting reports, which have been laid before the Federal Council. Three classes of labour are dealt with in these reports—Javanese, Chinese and Indian. Javanese labour only came under the supervision of the Immigration Department on March 31st last, and it appears that there is some deficiency of exact information with regard to it, and a good deal of ignorance on the part of employers and others as to the terms of the Netherland Indian Labourers Protection Enactment, which was passed last year. The labourers engage under a contract of service which is executed before a Dutch official in Java. And this requirement appears to be an effective preventive of kidnapping. But there are some complaints of misrepresentation on the part of the native recruiters, and trouble is caused by the fact that the contracts are drawn up in Dutch. The health of the Javanese is satisfactory, the climate of the Federated Malay States being very much the same as that of their own country. They earn good wages which should enable them to save substantial amounts, but the majority of them are improvident and addicted to gambling. Mr. Parr thinks that the employers generally treat the Javanese well “from motives of humanity, or self-interest, or both, and also because the Javanese labourer is of an independent nature, and somewhat inclined to resent ill-treatment.” In the words of one witness, “It is not possible to make a slave of him.” Summing up his conclusion, Mr. Parr expresses the conviction that the Javanese, in addition to being a good labourer, is a most desirable settler in the Federated Malay States, and he urges that every possible measure should be taken to encourage immigration, and to render service under indenture as inviting as possible.

The account of Chinese indentured labour is less satisfactory. The demand for this form of labour, which had almost reached the vanishing point, has recently revived owing to the spread of rubber cultivation and the scarcity of other labour. Mr. Parr proposes the substitution of the "kangany" system of recruiting, under which Chinese trusted by the employer proceed to China and there enlist their own relatives and neighbours—a system well known in connection with Indian labour both in the Federated Malay States and Ceylon—for the employment of professional recruiters, who have an ill name among their countrymen, and are known as "sellers of young pigs." Failing this, the establishment of Government depôts in the treaty ports is suggested. Serious abuses have occurred on estates on the Kurau and Krian rivers, whose remoteness has rendered possible a degree of severity which cannot exist in more accessible districts. On these estates the indentured labourer is often practically at the mercy of Chinese sub-lessees of part of the cultivated property, and is exposed to many hardships without the protection afforded by adequate inspection. Rubber, however, is now being substituted for sugar in these districts. The estates are gradually coming under European control, and the system of letting to Chinese, with its attendant evils, is dying out.

---

The recruitment of Indian labour under indenture for the Federated Malay States was discontinued under instructions from the Secretary of State, on June 30th last, and Mr. Parr's report affords ample evidence of the necessity for this step. The principal consideration which led to its discontinuance was the very high death-rate among indentured labourers, and this is ascribed largely to the attitude of despondency general amongst them. They found themselves working side by side with free labourers, who earned higher wages for a shorter day's work, and were free from the restrictions imposed on the indentured coolie. Many of the stronger and healthier coolies deserted, leaving behind the weaker or sickly ones, with the inevitable result of raising the general death-rate figures. An appendix to the report deals with one very bad case of the treatment in which drastic punishment was meted out to the guilty parties. Mr. Parr's general conclusions on the subject are as follows:—

"In my opinion, indentured Indian labour is no longer required in the Federated Malay States, and the abolition of the system will lead to a healthier state of the labour market, as unhealthy or unpopular estates will have to pay higher wages than estates with a better reputation for health or treatment. Recruitment in India of free labourers by the Indian Immigration Department should

continue, in order to assist newly-opened estates in obtaining a labour force, but the majority of Indian labourers would be recruited as in recent years by 'kanganies.' "

---

It has been decided to deal at once with the question of the Chinese, who have come to the Straits Settlements on contracts made before leaving their country. It is clearly desirable that the Colonial Government shall exercise some supervision in such a matter, and not leave the emigrant to the mercy of any agreement which he has signed, whatever its provisions. A bill has accordingly been introduced, the object of which is to give the Government the same control over such agreements made outside the colony as it already has, under the Chinese Immigrants Ordinance, over those made within it. Under this bill no contract made outside is to be valid, except under conditions which secure that the immigrant will understand the nature of the engagement.

---

The Straits Settlements Freights and Steamships Bill is a heroic effort to deal with a shipping conference which uses the deferred rebate system as a weapon. The particular procedure adopted by this conference is of a peculiarly drastic nature. There is evidence that in addition to the ordinary rebates, there is a further secret rebate which is given to a limited number of privileged shippers. The effect is plain enough. The conference by this arrangement is able to shut out independent steamers, and naturally has advanced the rates considerably. The plan of the Government is to levy a duty of 20 per cent. of the freight on all bills of lading, which will be repaid to those traders who are not parties to the combination, and to enable all shippers to recover deferred rebate for any shipments by the conference lines, even if they have used other steamers. The measure is founded on the principle that anything done in restraint of trade is against public policy, and that the arrangement in question is an act of that kind. On the other hand, it is argued that the legislation is an interference with freedom of contract, and sets up an extraordinary procedure for which there is no example elsewhere. Between these two considerations it is clear that some form of pressure is wanted to compel the conference to meet the general trading community in a reasonable spirit, and that the particular plan embodied in the bill could be dropped when this object is realised. The bill, in fact, is used as a "bludgeon," and it is to be hoped that the parties can be brought to terms by a reasonable compromise.

The Festival of Empire will provide an attraction of a novel character in the "All-Red Route Railway," which will consist of an electric mono-railway flanked on each side by scenery representing the different parts of the empire and their industries. The line will be about  $1\frac{1}{2}$  miles in length, and along it will be stations which will be used to exhibit the buildings and products of the various countries. The construction of this scenic railway will cost £25,000, and the council trust that the dominions and Crown Colonies will provide the buildings and exhibits. Presumably, the line will be of a sedate character, as the steep gradient beloved of the populace in other places would interfere with the tranquil appreciation of industrial progress. A number of the metropolitan boroughs are organising scenes in the Pageant of London, and there has been so much practice of this kind recently that the results are sure to be effective. The selection of subjects suggest local associations, and no doubt it is for good reasons that the "Rise of the English Theatre" will be shown by Ealing, and the "London of Merrie England" by Lewisham, and so forth; but it would require a profound knowledge of the history of London to give the right explanation in all cases. In the first scene there is to be a great gathering of representatives from all parts of the Empire. This should be an impressive spectacle. There will be a varied series of entertainments and receptions for visitors from overseas, and it is to be hoped that all our possessions will help to make the exhibition a complete and attractive one. From a business point of view, the opportunities for advertisement are excellent.

---

In an article on Marine Insurance in our issue of October, 1908, we pointed out that it might be advantageous for Colonial Governments to establish a common fund and organization of their own as a means of awarding loss from sea perils, and obtaining security for the value of consignments. This has now become an accomplished fact. A scheme has been formulated and has received the approval of the Secretary of State for the Colonies under which all Crown colonies which insure against marine risks will contribute at fixed rates of premium to a Marine Insurance Fund, under the control of the Crown Agents, instead of paying outside underwriters for protection against loss. At the outset the rates charged will be very much as they are at present, but if, as it is anticipated, the arrangement proves to be a financial success, a reduction in charges may be made in the near future, and it is hoped that eventually the fund will be large enough to carry the risk of all shipments with very little contributions from the Governments participating. To guard against the danger of financial embarrassment in the early stages arrangements have been made to limit for a time the risk on each

vessel, and, until it is properly established, the solvency of the fund will be based on the reserve securities held by the Crown Agents. It is proposed to give exactly the same protection to the assured as in the past, and the terms and conditions of the policy will, *mutatis mutandis*, remain unaltered. Claims will receive careful consideration, and will be settled promptly when supported by proper evidence. In all respects the scheme possesses features of great interest, and it seems likely that Colonial Governments will obtain eventually considerable advantage from the new undertaking.

---

In our last number we remarked on the unsatisfactory character of the news which is sent out from this country for colonial consumption. Since then we have seen an official complaint from a colony which pays for a supply of telegraphic news, that the greater part of what is received is "not news, but simply the daily rambling remarks of the press," and that with an excessive amount of repetition. Furthermore, there is sometimes no continuity in the accounts, and results are given without any explanation of previous circumstances. An instance is given in the statement that "the insurgents have taken over the management of the Regulation State Convention from the Regulars, at the same time recognising the national leadership of Roosevelt." This, it must be admitted, is a rather cryptic piece of information by itself for a community which cannot be expected to watch American politics intently. The cricket news is represented by such hieroglyphic fragments as, "Players, 119," "Kent drawn," but as it is not stated what elevens are playing, the reader cannot get much satisfaction. It is surprising that the news and telegraphic agencies cannot do better.

---

The Stationery Office have issued two volumes of coloured plates of the "Flags, Badges and Arms of the British Dominions beyond the Seas." (Part I. Flags and Badges, Price 3s. Part II. Arms, Price 5s.) The Arms and their "blazons" are of considerable interest, and may prove a source of amusement to the irreverent. It would be hard to find a more striking conjunction of old and new than the assignment to the very youthful province of Saskatchewan of Arms thus described:—"Vert three garbs in Fesse Or, on a Chief of the last a Lion passant guardant Gules." But this must yield place for mystery and magic to the description of the Arms of Queensland. "Per Fesse the Chief Or, the Base, per pale, Sable and Gules, in Chief a Bull's head caboshed in profile muzzled and a Merino Ram's head respecting each other proper, the dexter Base charged with a Garb of the first and the sinister Base on a Mount or Pile of Quartz, issuant therefrom a Gold Pyramid, in front of the

Mount, a Spade surmounted by a Pick saltirewise all proper." Ceylon is represented by "on a Mount Vert between a Grove of eight Cocoa Nut Trees and Mountains, in perspective an Elephant affrontée all proper." Mauritius has for one of its supporters "a Dodo per bend sinister embattled Gules and Argent," while British Honduras rejoices in "two Negroes proper breeches Argent."

The difficulties of the native official when he endeavours to rise to the height of the English language are notorious, but a request for leave of absence to attend a brother's funeral should be easy enough. The following letter, however, shows the result when the literary style is attempted, apparently with the help of a dictionary of choice phrases.

"Sir,—I have the honour to request you that I did not receive any answer of my petition as yet. Though I am flagrante delicto, aut fiat justitia ruat coelum, my younger brother has gone articulo mortis. Ipso facto O! tempera O! mores. Does the life of a man go out like a candle? Sic transit gloria mundi that veni, vidi, vici.

"Now please arbitrium send a man on my post, that may I do his proper work at home, it is a outrance affaire d'honneur which is agenda for your pertinently consider."

#### TO AUSTRALIA.

Australia, thou hast enriched thy store;  
 Hast felled the forest, ploughed the desert, plann'd  
 To link thy peoples by an iron band  
 And gathering up their ample harvests pour  
 These treasures of thy lap from shore to shore  
 To speed their freights for many a distant strand—  
 Corn, wine and wool and gold. O teeming land  
 Of boundless wealth, what canst thou covet more?  
 Ah, store of riches is an idle boast,  
 If courage fail and well-knit valiance.  
 Up then and gird a sword upon thy thigh  
 To match thy pride, for fear some alien host  
 Essay to spoil thy fair inheritance;  
 So shall thy name and prowess never die.

H. W. J.

## IMPERIAL FEDERATION.

THE Conference of 1907 put many new ideas in motion, and left behind it a substantial achievement. But it never discussed or used the term Imperial Federation. It established a permanent Imperial Conference. It thereby placed on a definite basis what previously, to use Sir J. Ward's words, had been looked upon as a sort of irregular assemblage of the responsible heads of the different Governments. It also established a Secretariat to prepare the work of the Conference in the intervals between the sessions. There was a good deal of discussion as to the constitution of this body, and in deference to the opinions expressed by the Australasian representatives the staff of the Colonial Office which deals with the dominions has been definitely separated from that which deals with the Crown Colonies. Mr. Deakin contended for an altogether separate office and a wider constitution of the staff. But this point is one of machinery rather than of principle. There was no suggestion from any quarter that the Conference should have wider powers than its predecessors. There were, on the contrary, clear indications of a desire to limit it strictly to the rôle of a merely consultative body. At the outset the name "council" was objected to and "conference" preferred, on the ground that the former would seem to indicate too large an assumption of authority.

There has, however, been recently a widespread renewal of the discussion of some stronger form of federation. In this country the idea is connected with the speculations as to the devolution of some of the powers of the Home Parliament. When so much is in the melting-pot, it is natural that the figure should arise of an Imperial Legislature relieved of parochial duties, and devoted to the greater affairs of the country and the common interests of the Empire. The constantly increasing interest in trade and defence questions promotes a corresponding feeling overseas. There is no doubt that the subject has a strong attraction for thinking men, and it is a healthy sign that it should be so. The King's subjects everywhere are conscious of

common ties, sympathies and objects, and many want to give form to this feeling by the creation of a body politic.

The advantages of union are being made more prominent year by year by the increasing range of international activities. While war is less likely to break out for inadequate causes than formerly, its effects whenever it does occur are more widespread and disastrous. So long as this is the case, it is a vast gain to civilization that so much of the world is preserved from internal war—so much secured open to peaceful trade. But how can the Colonies help this country to decide the question of peace? At present every voter in England can influence the decision, and the populations overseas cannot influence it at all. This is undoubtedly a grave defect in the system, and, while it could be disregarded when the Colonies were small and weak, it becomes more and more illogical and perilous every year to leave the matter in the old position. There is a Committee of Imperial Defence, on which the dominions are represented; but what is the use of that if we do not secure their adhesion and support in case of war? Let us remember that the great colonial world as we know it has practically grown up since England's last serious maritime war. We cannot now simply rely on the fact that all the colonists are the King's subjects, and presume that they would accept all the consequences of the connection. For this there must be clear consent and co-operation. The British Empire is sometimes compared with the Roman, but the Roman was held together by force. The nations had no part in the government, and when the force which held them together weakened they fell into a decay of energy. In our Empire the cohesion is not of force, but of free accord, and each member develops itself naturally. But political combination can only be secured by some central institution. The absence of it at present is illustrated by the trend of events in defensive matters. At the Conference of 1887, the Australasian Colonies were willing to pay a subsidy to the Home Government for the purpose of strengthening the Australian squadron. The ships so provided became the property of the Admiralty, and in the event of war were at its entire disposition. The scheme propounded by Mr. Hoffmeyer at the Ottawa Conference of 1894 similarly contemplated a scheme of all-round taxation for the support of the Imperial forces. But nowadays all the preparations and supplies are in the nature of local defence. The ships and the men are to belong to the dominions and to be under their orders. The movement for stronger defence is sound and welcome, but it must be recognised that it is on new lines. There is a clear divergence. If it goes much further, there is a danger that the unity of the Empire will be put aside by the assertions of scattered interests.

These and many other considerations, which it is unnecessary to set out, show the rising importance of common distribution and joint

action. On the other hand the growing spirit of nationalism has to be reckoned with. The Dominions are naturally and properly developing marked individualities. Few would suggest that one legislative or executive body would be conceivable as a working instrument for the whole assemblage. Such a union as there is in the United States is clearly out of the question. There the control will assert itself, if need be, by force. It is conceivable that a legislative and executive might be created with specified and limited powers, to deal with foreign relations, defence, and subjects of common concern, existing concurrently and side by side with the present machinery for the management of local affairs. There are not wanting cases of such a partition of powers. As a mere matter of machinery, the details of an arrangement could be evolved. Distance is not a fatal difficulty. Journeys almost as long in point of time have not prevented representation in other cases. The difficulty is more fundamental. In a previous number, issued after the Conference of 1907, we referred to the consideration that Imperial questions properly so called cannot excite the keen interest which attaches to local politics. If a Federal Parliament could be formed it would not attract the best energies and abilities of its territories. The statesmen who are powers in their lands would be out of it. They could not serve in two houses, and they would choose the one which deals with the home questions. Similarly the class of voters would show little interest in a federal chamber as compared with that which settles their education, their taxation, and all their domestic policy. Federation in this sense, therefore, implies a surrender of power from a body which is effectively controlled to a body which is not, and this is too much to ask from communities which prize their independence and individuality. These are the reasons why federation of this sort makes no practical headway. Since about 1870 it has been preached by a number of enthusiasts whose ideals have been unquestionably high. But no one has shown how to create a live thing.

It follows from this that the body which should represent the Empire cannot have a final authority. All acts must be legalised and all moneys raised by the local legislatures in their respective territories. Consent is the basis of the scheme, and must be given in full. But this condition leaves a great field to a central council. The aim is not one government, but one society. The first object would be to prevent complaints of neglect or injustice on the part of the home authorities towards the Dominions in connection with foreign negotiations about colonial rights. In the past practically every case of the kind has led to severe attacks, and the result has unquestionably been to diminish the affection felt for the mother country. There is a vast difference in the point of view. Great Britain undertakes the responsibility for war; she knows by

experience what it means, how easily an unyielding diplomacy may bring it about, and how enormous the cost is compared with any counter advantages. The colonies either do not fully appreciate this, or feel that they are involved in far less risk. More than once in our own time war would, undoubtedly, have been brought on if Great Britain had backed up the colonial demands with the persistency which she was urged to show. So lately as 1907 the Premier of Canada stated: "We take the record of diplomacy in so far as Canada is concerned, and we find it a repetition of sacrifice of Canadian interests. We have suffered on the Atlantic. We have suffered on the Pacific. We have suffered on the Lakes. We have suffered wherever there has been a question to be discussed between British diplomats." No doubt concessions have been made, but it would be idle to argue as if diplomacy turned solely on the merits of the case. The moral claims of right have not so far entirely displaced the advantages of might, and time and circumstance have still to be weighed. Moreover, Judge Langley, a distinguished Canadian authority, after an exhaustive examination of the cases in which Great Britain has been popularly supposed to have made a diplomatic sacrifice of Canadian interests, has come to the conclusion that no substantial ground of complaint exists. It is in any case very doubtful whether the average Canadian, if he weighed the risks of war and the possible result to his beloved dominion, would express any regret at the present day that British diplomatists had come to terms with their adversaries. In Australasia the trouble has been mostly caused by the assertion of a sort of Monroe doctrine over the South Seas—a doctrine which we would all like to see carried out, but which rests ultimately on force if there is any competition. But all along France and Germany have put in contrary claims, and to those who have followed the course of events it is clear that much of the feeling which prevails in Germany against this country dates back to the days when Bismarck fought fiercely against the Australasian demands for Samoa and New Guinea. In such difficulties, what is Great Britain to do? Is there any sort of all round guarantee to support her? If she sticks up for Canada in an Alaskan matter, will she get the enthusiastic support of Australia? If she runs the risk of warfare for an Australian claim, will Canada go with her? There is no security for this. The intention is always that the British taxpayer, whose own interest in the matter is negligible, should bear the brunt, and be thankful for any help that may be volunteered. On the other hand, the Dominions on the outbreak of a serious war would feel the moral effects of a weak political connection. They, too, have their perils, and have no guarantee that the Empire as a whole will support them in any trouble which may attend the claims of a "White Australia" or a "White Canada" or the dealings with native populations.

The position is obviously unsatisfactory. It could be greatly improved by an arrangement under which the Dominions would be represented in the councils of the Mother Country.

The present machinery provides a conference which meets once in four years and a secretariat which prepares work for it. A body which meets at this lengthy interval, aided by a staff of a departmental character and without pretensions to representativeness, is clearly inadequate for the purpose of taking part in the councils of empire. It was not created for that purpose. Mr. Secretary Stanhope's idea was to bring together the leading political chiefs of the colonies to discuss the subjects of defence and communications. He expressly deprecated the discussion "of any of the subjects falling within the range of what is known as Political Federation." The moral significance of such a meeting rightly counted for a good deal, and the new step was welcomed with enthusiasm. But for continuous working purposes the ideal was too high. It cannot be expected that Premiers can or will absent themselves frequently from the places which they represent. They are dependent on the popular will, and cannot long leave the field to their opponents. What is wanted is the strengthening of the continuous body. The first thing is to make it representative. Without going the length of setting up a legislative body, there is one strong and clear reason for a federal council. It would represent the participation of the overseas populations in the deliberations. It is immaterial from this point of view whether negotiations or deliberations would be improved by such machinery. The main object is to secure as far as possible the willing assent of all the parties to whatever is done. We do not nowadays rest the case for extensions of the franchise primarily on property or intellectual or any other personal qualifications. It is recognised that the reason for extending the vote is to bring in a larger body of the population, and so to ensure that solid support without which no government in civilised countries can be stable and effective. If this principle applies to a territory which is more or less compact, it is doubly important in the case of territories which are widely scattered. The further away a man is from the central seat of administration, the more difficult it is to excite his interest in the things that are done there. At present, if the truth must be told, the great bulk of our white population oversea is more or less apathetic about matters which appeal to Imperial spirit. There is nothing surprising about this. They have many difficulties to conquer and much hard and engrossing work to do. Their chief and best literature relates to the requirements of their daily life. There is, on the other hand, an increasing amount of wide public spirit among the leaders of opinion. It is impossible to contrast the utterances of to-day with those of a quarter of a century ago without seeing that a better feeling exists among colonial states-

men towards this country and the idea which it represents than was the case then. In Canada, Australia and South Africa there was a continuous stream of bitter attacks on the reputed acts and supposed objects of ministers here. A more sympathetic view is now taken of the many difficulties with which this country has had to contend, and which were not and could not be appreciated by populations lying remote from them. The improvement in feeling, welcome as it is, is, however, mostly on the top. The masses remain indifferent. Something is wanted to bring them into view of a larger horizon, and the only means of doing so is to give them a direct interest in the affairs of the Empire at large.

The Dominions are already represented here by their High Commissioners and Agents-General; but this fine material is not utilised as fully as it might be. They are not regarded as constitutionally the medium of communication between the home and the overseas Government. The Governors remain the sole correspondents except by courtesy of the Secretary of State. A copy of a correspondence may be sent to a High Commissioner, but it is a matter of favour and it is not always done. So far as the official correspondence is concerned, this arrangement must continue; the Secretary of State must deal with the Sovereign's representative. But there is much to be said in favour of making greater use of the experience and influence of the Dominions' representatives by giving them a more definite *status* in this country. They would by themselves form a very strong body for the purposes of representing the Dominions on all ordinary occasions. It would be well worth while to consider the possibility of an arrangement under which they would be associated with the present Secretariat. No one who has studied the recent blue-book can doubt the ability of the Secretariat to organise the questions and keep the correspondence alive, and if to this could be added the feature of representation of the Dominions, a federal council would be secured which would constitute definite evidence of union for common purposes. The ordinary monthly meetings of the Pacific Cable Board, which are attended by Imperial and Dominion Representatives, are a type of what might take place. Such an arrangement would satisfy the demand that the Dominions should have a hand in the continuous work. It would also go far to facilitate the work of the conferences. To such a body might be added temporarily any political chiefs who might be on a visit to this country.

It would further be desirable to invest the council with a formal constitutional character. There is a way of doing this. It is open to the King to constitute a committee of the Privy Council "*ad hoc*," *i.e.*, for any particular purpose. If the council were established in this way, it would at once take its place in the recognised scheme of Government. At the same time it would be clear that it could only

collect and advise. The Conference would be the sole determining authority.

There is a question of a somewhat domestic character which may be referred to in this connection. Some dissatisfaction was expressed from the first with the existing constitution of the Secretariat, on the ground that it is part of an office, which, so far as volume of work is concerned, is mainly concerned with the Crown Colonies. It is needless to say that the administration of these possessions, which is carried out with varying degrees of detail, but always with the recognition of the paramount authority and ultimate responsibility of the Secretary of State, differs fundamentally in spirit and method from the negotiations which are conducted with the possessions which have been granted self-governing powers. But the difference is perfectly clear and well recognised. There seems to be a sort of suspicion that officials who have had or may be in contact with experiences of Crown Colony business will apply the same methods to the Dominions. It would be inexcusable if this occurred. But there is no reason for supposing that it has occurred. No Dominions representative who has had experience of the matter has alleged it. Bitter attacks have, from time to time, been made overseas on the Colonial Office. It has been accused of various sins, of which a well sustained apathy is the least. But when the occasions which have provoked these indictments are examined, it is clear that they had nothing to do with the contaminating influences of autocratic government. Mr. Deakin, at the 1907 Conference, complained of a lack of sympathy on the part of the Colonial Office towards the Dominions. He instanced "the case of Alaska in regard to Canada, and the New Hebrides and Pacific interests in our case; and of Delagoa Bay in South Africa." Now, these questions were one and all matters involving grave questions of foreign policy or home interests. They were not, in fact, settled by the Colonial Office, or even materially influenced by it. In Australia the things that rankle are the alleged neglect of their interests in the South Seas. On this view such places as New Guinea, Samoa, and the New Hebrides have been unnecessarily more or less surrendered to foreign Powers. This is not the place for examining whether this is true. The only point that need be made for present purposes is that these were matters of foreign policy which were settled by the Cabinet of the day. This shows, at any rate, that the institution of a separate department with the Prime Minister at its head would be no panacea for such troubles. They always have been, and must in their nature be, dealt with by the Prime Minister. There are also technical subjects, such as merchant shipping legislation, in which the Colonial Office has practically had no hand. It is no exaggeration to say that in all such cases the department has done all that it could to support the contentions of the Colonies. The public hardly realises the extent to which the offices of this

country carry on a wordy war with one another. Each has its own considerations, and stands up for them for all that it is worth. If it cannot get its way, it endeavours to induce its political chief to engage in knightly battle on its behalf with the head of the opposing clan. The proceedings on such occasions are veiled from mortal eyes, but whatever the result the department has done its best.

It does not seem, therefore, to be in any way a vital matter that the Secretariat should be in a separate office. This question turns on somewhat domestic considerations. It is a small staff of some nine officials, and is recruited from a much larger body in accordance with the personal aptitudes which are brought out by experience. It would certainly be practicable to constitute an entirely separate department, nominally under the Premier, to deal with the Dominions. Whether this arrangement would improve the staff or render the supervision more complete than it is now, is at least open to question. Furthermore, there is a vast body of experience and research in business, scientific and medical questions, which is common to both sides, and it would be regrettable if co-operation in these great fields of non-contentious and eminently useful work were made difficult. No doubt any views which the Dominions may put forward will receive the most sympathetic consideration, and as the matter is one of machinery only, it would be possible to meet them; but it may be suggested that, before any change is made, the whole work done by the Dominions department should be reviewed with regard to the facilities which are given to it by the present grouping.

This matter would become of minor importance if the Secretariat were reinforced by the available Colonial representatives. But it may further be pointed out that the Dominions themselves have an interest in the Crown Colonies. There is much intercourse with them: there will be much more, and in our time. The Empire as a whole should stand together. Australia is interested in Fiji; Canada in the West Indies; the South African Union in all Africa. There is no telling how far the Union may go in due course. Sentiment and business combine to expand it. Future problems of administration will in many respects afford opportunity for wide consideration and the participation of the British race wherever it is. Carlyle had a lurid way of painting things, but there is sound sense under the colours, and we will hazard a quotation:—"There are portions of the general earth, where the children of Britain now dwell; where the gods have so far sanctioned their endeavour, as to say that they have a right to dwell. England will not readily admit that her own children are worth nothing but to be flung out of doors! England, looking on her Colonies, can say: 'Here are lands and seas, spice-lands, corn-lands, timber-lands, overarched by zodiacs and stars, clasped by many-sounding seas; wide spaces of the Maker's building, fit for the cradle yet of mighty Nations and their

Sciences and Heroisms. Fertile continents still inhabited by wild beasts are mine, into which all the distressed population of Europe might pour themselves, and make at once an Old World and a New World human. By the eternal fiat of the gods, this must yet one day be; this by all the Divine Silences that rule this Universe, silent to fools, eloquent and awful to the hearts of the wise, is incessantly at this moment, and at all moments, commanded to begin to be. Unspeakable deliverance, and new destiny of thousandfold expanded manfulness for all men, dawns out of the Future here. To me has fallen the godlike task of initiating all that: of me and of my Colonies, the abstruse future asks, Are you wise enough for so sublime a destiny? Are you too foolish?"

## KEDAH, PERLIS AND KELANTAN.

THE first Annual Report on the State of Kedah since its transfer to Great Britain under the terms of the Anglo-Siamese Treaty of 1909, has been presented to Parliament, and the Acting Adviser to the Kedah Government, Mr. W. George Maxwell, has taken the opportunity to give a general account of the country in addition to recording the principal occurrences of the year. The Muhammadan, and not the Christian, calendar is in use in Kedah and the Report is consequently described as being "for the year 1327 A.H.," which corresponds to the period from January 23rd, 1909, to January 12th, 1910. Mr. Maxwell prefaces his report with a sketch of the complicated and troubled history of Kedah. Legend has long connected the Malay Peninsula with the Golden Chersonese and with the Land of Ophir.

"The truth, however, is that until comparatively recent years the Malay Peninsula was a place to be carefully avoided. Before the twelfth century, the coast was probably only inhabited by the sea-Sakeis, now nearly extinct, who were certainly a treacherous and murderous race, if not actually, as stated by the Portuguese, cannibals. The Malays who began to populate the Peninsula in scanty numbers in the twelfth century were pirates, who, when any vessel fell into their hands, seldom scrupled to kill the crew as well as plunder the cargo. There was nothing to export. When, therefore, the ships of the Chinese and Japanese merchants came sailing down from the China seas on the north-east monsoon, and the ships of the Indian and Arab merchants came sailing down on the south-west monsoon from the Indian Ocean, it was with good reason that they avoided the Malay Peninsula and sought some port on the civilised Javanese coast where they could exchange their merchandise, and then sail back to their own ports on the following monsoon."

The local "Annals" affirm that the Kingdom of Kedah was founded by men who came from the West in a fleet under a leader named Marong Mahawangsa, whose descendants extended the

boundaries of their Kingdom north and east and south. Previously the country had only been inhabited "by men who had long canine teeth and cannibal propensities." This conquest may have taken place in the thirteenth century. Kedah is mentioned in a Javanese poem of 1365, and its first mention by a European writer appears to be in 1516. It suffered many vicissitudes, being subject at one time to the Sultan of Malacca and at another to the King of Siam, and was overrun in turn by Achinese, Portuguese, Bugis and Siamese. In 1821 it came permanently under the rule of Siam, but in 1843 the Sultan, who had been in retreat at Malacca, was allowed to return and to re-assume the government of Kedah proper, one of the four parts into which the ancient Kingdom was divided. To this was subsequently added the district of Kubang Pasu. Of the other two parts of the former Kingdom Perlis became a separate Sultanate, and Setul a part of Siam. Thanks to a system of finance, lax even for an Oriental country, Kedah became gradually more and more deeply involved, and matters were brought to a crisis by expenditure on a lavish scale on the occasion of the celebration of a number of royal weddings in 1904. The following year a loan of \$2,600,000 was made by Siam, and Mr. W. J. F. Williamson, Financial Adviser to the Siamese Government, came to Kedah and "in a marvellously short time reduced chaos to order." By an edict of July 23rd, 1905, a Council of State was set up to assist the Sultan in the administration of all public affairs, and this continues under the present *régime*, with the substitution of a British for a Siamese adviser. Mr. Maxwell gives a list of the matters dealt with by the Council at its 23 meetings during the year under review, which shows how important its functions have become.

"The State is more purely a Malay State than the States of the Federated Malay States. The Muhammadan, and not the Christian, calendar is used. Friday is, as well as Sunday, a day upon which the public offices are closed. The language of the Legislature, the Courts and the public offices is Malay. There are only ten European officers in the State, and of this number three are police officers, two are financial officers, three are professional officers (the State Surgeon, the State Veterinary Surgeon and the State Engineer), and the remaining two are the Adviser and the Assistant Adviser. There are a few Tamil officers in the Medical and Postal Departments, but with the exception of these officers, of the Sikh detachment of the Police Force, and of a few interpreters and detectives (Chinese, Siamese and Tamil) all the Government servants are Malays; and of the Malays perhaps not more than half a dozen understand any language except their own."

One of the most interesting items in the Report is Mr. Maxwell's account of the recent abolition of forced labour.

“ Forced labour (*krah*), if exacted in moderation, and for Government works, is perhaps in a country, where a voluntary labour supply cannot be obtained upon payment of a fair salary, not without advantage to the State ; but in Kedah, by reason of the power of the *mukim*-holder to exact forced labour for his private use, and in the entire absence of any control over the *mukim*-holder, it has been nothing less than an unmitigated curse to the country.

In recent years forced labour has been but little employed upon Government works, the principal exception being in the case of the supply by forced labour of telegraph poles, which were obtained from certain special *mukims*, the *raiahs* of which were called upon to perform no other forced labour. The only instances of forced labour for Government purposes which I found upon my arrival were that some schools in outlying *mukims* were being built by paid forced labour for the Public Works Department, and that all the men used for the transport of boats taking officers upon Government service up and down the Padang Trap, Pendang and Muda rivers were *krah*-ed and not paid. The privileges of the *mukim*-holders, of course, were unabated. The position, therefore, was that the system was of little practical use to the Government ; deprived it of a considerable annual revenue that might otherwise be obtained from the land-tax, and solely benefited the *mukim*-holders at the expense of the unfortunate *raiahs*.

I ascertained soon after my arrival that all the members of the State Council disapproved of the system, and that two or three attempts had been made to persuade His Highness the Sultan to abolish it. His Highness, however, was of opinion that the power to exact forced labour was a necessary part of the royal prerogative, and declined to alter the system in any way.

At a Council Meeting held on the 23rd August, a proposal by Syed Muhammad Shahabudin, Auditor General, that *krah* be abolished was carried unanimously subject to confirmation by His Highness the Sultan. A few days later all the members of the State Council had an interview with His Highness the Sultan, and, after some time, were able to persuade His Highness of the desirability of abolishing the system. There was some delay, partly owing to the fasting month and partly owing to minor difficulties, but eventually, on the 25th October, His Highness signed a proclamation abolishing forced labour in the State with effect from the 30th October. The notice was immediately printed, and copies sent to every *mukim*, posted in all public places and read in the mosques. It was, of course, welcomed everywhere. The effect of this important step cannot, I think, fail to have the most beneficial results, not only in setting the Malay agricultural class free from oppression, but in adding to the land revenue and in attracting immigration.”

But a difficulty perhaps even greater presented itself in the survival of a time-honoured system of debt bondage.

“ Among the institutions of every Malay State have been, since remote ages, those of slavery and debt-bondage. Both are common to the Indo-Chinese races, and in respect of both the custom is at variance with the precepts of the Muhammadan religion. Slavery is but of historic interest in Kedah, for it was abolished many years ago by a proclamation, of which I have been unable to obtain a copy or even to learn for certain in which reign it was issued. Debt-bondage is, however, still in force. Under the system the debtor, in consideration of the loan, enters into an agreement with the creditor to work for him until the debt is paid off. The debt is a genuine one, and can be traced to a *bona-fide* transaction; as, however, the debts are transferable, the original transaction is sometimes remote. It is a common thing for a debtor to seek service with a new master by the simple process of borrowing from the new master sufficient money to pay off the debt to the old master. The amount of debts vary from \$30 to \$150, the average being about \$60. In the majority of cases there is an express provision for the debt being diminished (*susut*) by a fixed amount every year, but these annual diminutions are very small, varying from \$2 to \$10. The debtor may be of either sex, and in many cases the debt is incurred by a man and his wife jointly and severally. Except in the case of the caretakers in the orchards, whose duties are little more than nominal, the creditor feeds, clothes and houses the debtor, free of all charges.

From the Malay point of view, the transaction is merely a civil contract by which a person who has no property to offer as security for a loan is able to obtain credit upon the security of his personal labour. It is true that by the law of the country a run-away debt-bondsman is liable to arrest and punishment, but then so, too, is an ordinary absconding debtor; for both are held to be guilty of fraud. Cases of ill-treatment of a debt-bondsman by a creditor are rare, and the debt-bondsman has exactly the same redress that any other person would have. (A slave, of course, in former days had not.) Since my arrival here on the 15th July, I have received petitions and personal applications of all kinds in hundreds, but of this number only four have been from or connected with debt-bondage. I enquired carefully into all four. Two were from women whose husbands had died and who were prepared to marry again, but whose prospective husbands were loth to undertake the responsibility of their debts. The third was a frivolous complaint by a somewhat weak-minded old woman, who had done no work for years, and who would, if turned out by her nominal employer, have been absolutely destitute. The fourth was from a young woman who had been severely beaten by her mistress for immoral conduct. In this case, the President of the State Council and I decided that the chastisement inflicted by the mistress had the effect of breaking the contract for personal service, and we sent the woman to her parents' house.

On the 1st Jemad-al-Akhir, 1310 (A.D. 1892) His Highness the Sultan issued regulations for the registration of all documents relating to sales, mortgages, loans, promissory notes and similar documents, and the fourth paragraph of these regulations provides that all agreements entered into by debt-bondsmen shall be registered in the land office of the district in which the parties reside. Failure to register an agreement does not, however, render it invalid, but merely makes the holder liable to a penalty of \$25 by the Court in which he may produce it for the purpose of any suit upon it.

Kedah has now before it the problem which its neighbours have solved: the Straits Settlements by the Indian Act. V. of 1843, Perak by the Order in Council of 1882, Pahang by Enactment XIII. of 1906, and Siam by the Law of the 1st April, 1905, for the Abolition of Slavery.

At a Council Meeting held on the 22nd Zulhij-jah, a resolution was unanimously passed that the system of debt-bondage was one which was detrimental to the progress of the State, and it was decided that no new agreements, by which any person agreed to work for another person in consideration of a debt, should be valid, that the best means of terminating the existing agreements be considered at a later meeting, and that an Enactment be drafted for discussion and later for submission to His Highness the Sultan.

Simultaneously, instructions were issued to the Courts that they were to take no action whatever in respect of suits arising out of bond-debts without the express permission of the President of the State Council, and to the police, that they were to take no action upon applications for the arrest of absconding debtors unless a warrant was first obtained.

Three schemes have been laid before the Council. The first is on the lines of a Statute of Limitations, and provides that debts incurred before a certain date (say, seven years) shall not be the subject of any action in Court; that in respect of debts of standing between (say) five and seven years, the creditor may only sue as if they were ordinary debts, and may not demand specific performance of the contract to labour; that in respect of debts between three and five years, the creditor may have the option either of suing for the debt or of compelling the debtor to work for another year from the date of the passing of the Enactment, in which case the debt would be extinguished at the end of the year; that in respect of debts between one and three years standing, the creditor be given a similar option, except that the term of labour be two years instead of one; and that in respect of debts of less than one year's standing, the creditor be given similar option, except that the period of labour be three years. The second scheme is on the lines of the Siamese law above referred to, and provides for the debt being reduced by a fixed amount in respect of every month's work performed. The third scheme provides for the

Government buying all these debts at a valuation to be fixed by arbitrators, and then remitting the debts.

Each scheme has its advantages and disadvantages, and the State Council, in assuming the responsibility of cancelling, for motives which will be unintelligible to the contracting parties, a civil contract, recognized by immemorial custom and voluntarily entered into by both parties, feels bound to act with fairness to both parties, and has not yet been able to arrive at a decision. It is impossible to make a hard and fast rule that will apply equally to all cases, for it is obvious that a debt by an old man or woman, the value of whose labour probably does not cover the cost of his or her maintenance, has a very different value from a debt of the same amount by a strong young married couple; and the State Council is seeking for the fairest possible rule. It must, therefore, be left to the next Annual Report on Kedah to record the action taken in this important matter. The principal evil of the debt-bondage system in Kedah is, I venture to say, not that it entails any harsh treatment of the debtor, but that it deprives him of all inducement to work, for it is not in human nature to work hard when hard work brings no reward."

The transfer of rights from Siam to Great Britain has been signalized by a curious piece of ceremonial.

"In accordance with ancient custom the Sultan of Kedah sends a tribute offering, known as the *Bunga Mas* (the golden flowers), or *Bunga Mas dan Perak* (the gold and silver flowers), to His Majesty the King of Siam once in every three years. The offering consisted of a golden tree and a silver tree, each about five feet high, with branches and flowers of formal design, and it was sent in charge of a responsible Kedah official from Kedah to Singora on elephants, and from Singora to Bangkok by steamer. His Majesty the King of Siam always received the tribute personally.

"When the transfer of the suzerainty of Kedah took place, the two trees had already been made, and at a meeting of the State Council held on the 23rd August, it was decided to ask His Excellency the High Commissioner whether His Majesty the King would be pleased to accept the tribute, which might be deemed to have a special interest by reason of its being the last of a series extending back to a remote past.

"A reply was received to the effect that the offering would be acceptable, and Tunku Muhammad Jiwa, who for many years past had taken the tribute to Bangkok, proceeded to Singapore on the 15th November in charge of the cases containing two trees, and the 42 spears and 24 shields, which by custom always accompany the offering. The cases were forwarded to the Colonial Office, and were, together with the *Bunga Mas* from Perlis and an offering from Trengganu, presented by the Secretary of State for the Colonies in person to His Majesty the King, who was graciously pleased to

express his admiration of the workmanship of the gold and silver trees."

The same paper contains the Annual Report of the Acting Adviser to the Perlis Government, Mr. Meadows Frost, who remarks that "at the time when the treaty was pending the Perlis people's only anxiety was lest they should not be included among the States to be handed over to the protection of Great Britain."

The report of the British Adviser in Kelantan, Mr. J. S. Mason, is published as a separate Parliamentary Paper. Mr. Mason draws attention to the satisfactory expansion of land revenue, which has increased from \$24,730 in A.H. 1323 (1905-6) to \$102,656 in A.H. 1327 (1909-10), but he adds, "There is much evasion of taxes. The present system of taxation combines the maximum of trouble in collection with the minimum of result. A simple method for a young country, it depends for its results too much on the efficiency of the native collectors." Noteworthy improvements have already been made in the administration of justice.

"The Courts were not satisfactory and compared very badly with the Courts in the Federated Malay States. With the exception of one Siamese Judge, all Court officials were Malays. The Adviser sat as a Court of Revision but heard no evidence first hand. In one Court it was a common practice to allow two cases to be taken at the same time; the evidence of witnesses was taken down by clerks; the Magistrates paid little attention until the pages of evidence were handed up to him. It was the universal practice for the clerks to write down the evidence: the Magistrates kept no notes. Statements made to me by the foreign residents in Kota Bharu made it quite clear that the public had little confidence in the Courts. The clerical staff had too much influence and was generally untrustworthy. Cases were frequently allowed to drag on for months. The Magistrates, on the plea of illness, were irregular in attendance, and there was no qualified Medical Officer to say whether absence from duty was justified.

"On the resignation of the Siamese Judge I arranged that the Assistant Adviser should take his place in the High Court and the Appeal Court, so that Malay Magistrates have now for the first time before them the example of a European Magistrate attending Court punctually and regularly and deciding cases with impartiality and without delay. Owing to resignations and dismissals the personnel of the staff is being gradually improved. There is now little or no delay with criminal cases. The work of the Courts has been so re-arranged that all police cases in Kota Bharu are now taken into the Central Court. All serious cases are committed to the High Court, in which a European officer sits, and all appeals go before a European Judge.

"The Muhammadan Court, which has had a bad record for years, was even less satisfactory. There were numerous complaints of

delays in settling cases ; charges of corruption and misappropriation are now being inquired into. It will probably be necessary to take away the jurisdiction the Court at present holds in cases of inheritance of land."

With regard to the population of the State, Mr. Mason makes the following remarks :—

"The Kelantan Malay differs considerably from the F.M.S. Malay. He is a tallish, raw-boned man, much more bonily-built than a Pabang Malay. The difference has been well compared to that between a cart-horse and the polo pony. The Kelantan Malay is capable of much continuous labour and in this respect resembles the Javanese. There is little doubt that, although imported labour is a necessity on large rubber estates, the local labour will continue to be used in larger numbers than in the Federated Malay States."

## BARO-KANO RAILWAY CONSTRUCTION.

WE have several times referred to the progress of this railway, which is extremely interesting, not only as opening up a vast territory, but as an example of a line built on the most economical principles. Nothing in fact but proof of the closest economy would have secured the consent of the Treasury to the outlay. For the following detailed account, which will, we are sure, be found valuable by all who may be concerned in similar enterprises, we are indebted to Capt. H. A. Mance, D.S.O., R.E.

Prior to the construction of the Baro-Kano Railway, the sole means of communication over all portions of Northern Nigeria not immediately served by the Niger or navigable portions of its most important tributaries, the Benue and Kaduna, was by native tracks, over which all stores had to be conveyed by head transport. These tracks were for the most part impracticable in the height of the rainy season, and at the best of times 15 miles was considered a good average day's progress. It became evident several years ago that further development of this Colony was impossible without improved communications, and the matter came into special prominence when the investigations of the British Cotton Growing Association brought to light the fact that Northern Nigeria was the most promising field for the production of cotton to meet the expanding requirements of our most important textile industry, now threatened with shortage of raw material owing to the increasing proportion of American-grown cotton required for American mills. In addition to the necessity for a cheap outlet for the products of the country, efficient administration was most difficult and costly, and there always remained the strategic difficulty of coping with any native rising with the small forces available under the existing adverse conditions of transport and personal travel.

To these primary considerations must now be added the discovery of a rich tin field in the region of Bucchi, some 140 miles east of the Railway under construction.

A large amount of official correspondence had taken place on the subject of Nigerian Railway construction, and a survey had been made from Baro to Kano via Zungeru before 1907. Various schemes were put forward and after consideration a 3 ft. 6 ins. gauge line was recommended over this route with a maximum gradient of 1 in 50. In May, 1907, Sir Percy Girouard, Governor of Northern Nigeria, formulated a railway policy in which he recommended the construction by the Public Works Department of the Protectorate, of a 3 ft. 6 ins. gauge railway from Baro to Kano, avoiding Zungeru, the present capital, the site of which ceases to be of importance as soon as a more efficient channel of communication than the Kaduna River becomes available. As the result of a survey, superintended personally by Sir Percy Girouard, it was found possible to adopt a ruling gradient of .7 per cent., or 1 in 143, for traffic going up country, and .6 per cent., or 1 in 166, for traffic coastwards throughout the first section of 111 miles. Construction was authorised in August, 1907, and ten miles of permanent way material were at once sent out. Thanks to very careful preparations and to the organisation of all the resources locally available, a full programme of work was carried out during the dry season 1907/8, thereby probably saving a year in the time required to complete the railway to Kano. An absolutely free hand has been given to the man on the spot as regards all engineering details including the alignment. Without this, such cheap and rapid construction would not be possible. It has also been decided to link up the Lagos Railway with the Baro-Kano Line by extending the former through Jebba and Zungeru to Minna.

The Niger at Jebba flows in two channels, one of which is now being bridged and the other will be traversed by train ferry till the traffic justifies the building of a bridge. The portion from Minna Junction to Zungeru has already been laid and railhead of the Lagos Extension is about half way from Jebba to Zungeru. The road bridge over the Kaduna at Zungeru is being strengthened and altered to carry the railway, and it is hoped that the systems will be linked up early next year.

Baro, the Niger terminus of the Baro-Kano Railway, is situated about 420 miles from the coast. At high water, from the beginning of August to the middle of October, it is accessible by steamers drawing from nine to twelve feet and containing up to 1,100 tons of cargo. For the rest of the year boats drawing four feet have no difficulty in reaching Baro, except for the months of April, May and June, when a draught of two feet was all that could be reckoned on. It was found, however, that there were only about two miles of shallows to be dredged to make the river available for vessels drawing four feet throughout the year, and that only some five miles of shallows stood in the way of a six feet channel all the

year round. A powerful suction dredger has therefore been obtained, by means of which it is hoped to maintain a channel for vessels drawing at least four feet, and it is a hopeful sign that the very small amount of work which was done by this dredger during the recent especially low river enabled the larger stern wheelers to work regularly up to Baro for the first time. With an available draught of four feet all traffic likely to pass over the Baro-Kano Railway for some time to come during the low river season can be easily handled by tugs capable of towing two barges each with a capacity of 100 tons.

---

### Delivery of material at Baro.

In view of the very rapid rate of progress on which the estimates for the construction of the Baro-Kano Railway were based, the serious question arose as to whether it would be possible to deliver at Baro during the high river the large quantity of material required for a whole year's programme. Some difficulty had been experienced owing to an exceptionally low river in delivering by three large steamers (commonly known as "branch boats"), supplemented by stern wheelers, the three thousand tons required for the 1907/8 programme, and the estimated tonnage for 1908 high river was twenty-three thousand, and for 1909 nearly thirty thousand. The possible causes of failure were many, and it was freely predicted that the programme would have to be considerably amended for this reason. The unfortunate early experience of the French on the Senegal River under somewhat similar circumstances showed clearly how serious might be the consequences of any miscarriage. Thanks, however, to the careful co-operation of the shipping firms and to favourable high river seasons in 1908 and 1909 all these fears have proved to be groundless.

The appliances for dealing with railway material on arrival at Baro were of the most primitive nature. All that could be done in the time was to provide sufficient stacking ground, no easy matter on such sloping ground—and to obtain a number of 12 ins. by 12 ins. timbers, about 50 feet long, for employment as gangways from the branch boats to the shore. When the first steamers arrived the level of the water was such that a steep pull-up was involved, but later on this disadvantage ceased to exist. An unlimited amount of absolutely unskilled labour was made available, and from twenty-two to twenty-four European foremen were detailed at Baro for the work of dealing with the first year's shipping. Of these foremen, nine were Royal Engineers and 16 in all were quite new to the country. Under the circumstances it was only possible to employ the most rudimentary methods, and for the first day or two progress was decidedly slow. It was found best to employ about 60 to 75 natives at each

hatchway, and at first it was necessary to employ a foreman at each hatchway and one on the stacking ground for each ship, but the latter was dispensed with after the first fortnight. Two shifts were worked, the first being 6 to 8.30 and 9.30 to 3 p.m., and the second 3 p.m. to 7 p.m., and 8 p.m. to midnight. A number of Kitson lights were provided for night work. They were found to be rather delicate and to require a skilled European mechanic in charge of them, but otherwise answered the purpose most excellently, except actually during tornadoes. The staff subsequently tried an acetylene flare light, which appears to offer considerable advantages on account of its strength and simplicity. Work was carried out on Sundays, usually one shift only, but it was found necessary to arrange for every European and gang to have one day a week off the works.

---

### **Discharging Rails.**

The procedure for discharging rails was to slide them in bundles of from three to ten, depending on the slope up to the bank, across a gangway consisting of two of the long timbers mentioned above spaced at about 15 feet interval, each of them having rails spiked along their upper surface and kept thoroughly greased. A hauling rope was fastened near each end of the bundles, and with a little practice the gangs on shore got in the way of keeping the bundle central with reference to the two timbers, or of adjusting any tendency to move aside or come up skew-ways. On the arrival of each sling at the bank, carrying parties were waiting in sufficient strength to take the rails to the stack beds at once, as an accumulation of more than a few rails on the bank resulted in impeding the work. The rail stack beds were most carefully prepared, the type usually employed consisting of four rail lengths of track side by side, the whole of the sleepers being carefully packed quite level. Owing to lack of space it was found necessary to have full layers in both directions throughout the stack, which was raised to a height of thirteen layers, or about 4 ft. 6 ins. Separate stack beds were provided for "special" rails and for the percentage of shorter rails from 18 feet upwards, and it is important to separate out all bent rails and stack them separately for subsequent straightening. A simple form of rail hook, made out of  $\frac{3}{4}$  iron and about 2 feet long, was found very convenient for handling the rails on the stack beds. Care must be taken that the ends of the rails are not burred by blows from a hammer.

---

### **Discharging Sleepers.**

Sleepers were carried ashore on gangways and can be stacked on almost any ground. Where space admits it is quicker and

more economical to throw them into piles. Time is also saved when re-loading, as sometimes two or three sleepers in a proper stack jamb together and have to be separated by a bar.

---

### Handling Heavy Cases.

Owing to the lack of facilities the discharging of cases weighing from 2 to 30 cwts. was a source of much trouble, two or three handlings being sometimes necessary, and the cases having occasionally to be broken up on the beach. The best way of dealing with these would be by a quick-acting steam crane direct into trucks. It is well worth building a small jetty for the purpose, capable of receiving a lighter alongside, and to arrange for all such cases to be delivered from the steamers into lighters.

---

### Handling Heavy Locomotives.

The most difficult problem was the discharging of the boilers, frames and tenders of the locomotives. These weighed up to 12½ tons, and the first consignment had to be got ashore from an insecurely moored steamer, over a clear span of 42 feet, then up an incline of 1 in 2 for 30 feet, along 40 feet of level, and finally lifted on to trucks. The only power available was one of the ship's winches, and less than a foot was available on board to receive the ends of the gangway timbers. The shore was reached by a gangway of four heavy timbers with rails spiked on top, the outer timbers having to be spaced only 9 ft. apart to fit the gangway of the ship. A cradle with smooth metal under-surfaces was constructed to slide on this gangway and provided with flanges at 9 ft. gauge. The heavy weights were carefully balanced on the centre of the cradle, to which they were lashed with wire rope. Large sheerlegs were erected on shore, 12 ft. by 12 ft. timbers over 50 ft. long being employed, and steel rope lashings and tackle throughout. The sliding track was continued from the gangway up to the sheerlegs, under which a siding was laid. The cradle was pulled from the ship's side to the siding by the main tackle of the sheerlegs, the angle of attachment of the sling which was passed round the cradle and its weight being arranged with very great care. As the blocks available for the first weights were much weaker than the rest of the tackle, every precaution had to be taken to avoid hitches which might bring indeterminate strains to bear, and a vital point to bear in mind is the disturbing effect on the ship's moorings caused by the use of the ship's winch for the main tackle of the sheerlegs. The use of steel rope lashings and tackle for sheerlegs required to lift regularly from 10 to 20 tons is strongly recommended. The second consignment of heavy weights was dealt with in a similar manner

without any difficulty, as stronger tackle was available, and owing to the higher river the clear span and steepness of the slope were much reduced. In 1909 the heavy weights were loaded direct into trucks from the steamers at a jetty erected for the purpose.

### Waggon Frames,

which weighed about two tons, were transferred from the ships to the tops of lighters and slid off on to carefully prepared stacking beds, from which they were later on slid under a derrick for erection.

### General.

In dealing with large quantities of material as above the secret of success is to look well ahead in the preparation of sufficient stacking beds, to insist on the economical use of the ground, and to be on the *qui vive* to repress the inevitable tendency of the carriers to get rid of their loads at the earliest possible moment, and thus by effectually blocking the entrance to the stacking ground very seriously retard the operations, which may have to be temporarily suspended to put matters right.

Arrangements were made to deal with three branch boats at a time. After the first few days it was found possible to deal with 500 tons a day with ease, and on August 31st a maximum of 870 tons was attained. The quickest boat averaged 355 tons a day for two shifts, or 25 tons per hour of actual work. The total number of natives employed at this time was about 1,200. A dressing tent on the site of the work saved a lot of time in dealing with minor injuries. Almost incredible to relate, in 1908 over 20,000 tons of material were handled with absolutely raw labour, with only one serious accident, which necessitated the amputation of a foot.

As regards the cost of handling, it was found impossible to analyse each class of work at the time, but with foremen costing £1 a day and native labour at 9d. there should be no difficulty in handling rails and sleepers at 1s. 2d. a ton, including the preparation of stack beds, stacking, and the clearing up operations frequently necessary after the periods of greatest stress.

### Discharging Locomotives from Lighters.

After the high river some locomotives were sent up to Baro in lighters and proved an awkward task to discharge, as the banks were very high at this time, and the barges had to be lightly loaded to reduce the draught. The procedure was to jack the weights high enough above the level of the barge to allow a gangway to be inserted underneath them, together with the cradle referred to above. The weights were then pulled up a very steep incline in the same way as before, with the exception that an insufficiently powerful winch had

to be employed for the main tackle. As this winch had no capstan drum three separate lifts had to be taken before the weights were deposited on the trucks. For this purpose, and to guard against accidents, safety ropes were invariably provided and kept tight, a most useful precaution, in view of the fact that the cylinder cover of the winch blew off on one occasion. The most serious difficulty in off-loading from lighters is due to their instability, as any deviation of the weight from the centre made them heel over badly. It is well worth while rigidly lashing a second barge alongside.

At a certain level of the river it was found possible to use an exit slipway, and to arrange to traverse the heavy weights by jack direct from the barge to the truck over intervening staging.

---

### **Plate-laying and Ballasting.**

The Baro-Kano Railway is being constructed as a pioneer railway, that is to say, the expenses of construction are cut down to a minimum, consistent with obtaining a railway capable of carrying all traffic in connection with the administration of the country, and such trade as is likely to develop during the first years of its existence. This economy has not been allowed to affect the most efficient grading and alignment, so that it will be possible, as the amount of traffic justifies it, to gradually strengthen the line and improve the accommodation to meet the requirements. One very considerable source of economy is in the ballasting, which is carried out with sand or any other suitable material available in the immediate vicinity of the line. It is only over a few comparatively short lengths, where the surrounding soil is entirely clay or black cotton ground, that ballast has to be brought by train. This saving in the actual cost of haulage is supplemented by the important reduction in the amount of rolling stock necessary for construction, a point of the highest importance. The extra cost of obtaining better ballast at the expense of a longer lead up to half a mile or even a mile is well worth incurring, but it may be found in rapid railway construction that shortage of labour may prevent full weight being given to this consideration. Ballasting was placed under the officer in charge of the Plate-laying District, and was carried out only a few miles in front of rail head.

---

### **Procedure.**

The procedure of ballasting and plate-laying is as follows:

The formation is trimmed up by the earthwork parties, and the line is re-centred with pickets left standing about 3 inches above the surface. At the same time level pegs are given every 200 feet on the straight, and every 100 feet—or even 50 feet—on curves. These pegs are best driven on the edge of the formation flush with the correct formation level, and marked by reference pegs painted white,

two such reference pegs being used at each change of grade. This re-centring and levelling is of the greatest importance, as the quality, rapidity and cost of the work depend on the track being laid absolutely straight, and as nearly as possible to correct levels in the first place. Next come the ballasting parties, who make a platform of the best material available, 8 feet wide on the top, with the surface or straight portions of the line 7 inches above correct formation level. In this way an accurate graded surface is prepared for track-laying, notwithstanding slight irregularities in the formation. In the centre of this platform there is left a V shaped groove or furrow (to which fact this ballast platform owes its local name of "The Furrow") for the purpose of leaving the centre pegs exposed to view, and at the same time guarding against any chance of the centre of the sleeper being packed higher than the ends. Accuracy of the grading and alignment of the furrow is obtained by putting in side pegs every 25 feet to mark the outer edges of the furrow, these pegs being levelled to the exact height by boning from the formation pegs. One European, with from six to ten locally trained natives, have no difficulty in doing from  $1\frac{1}{2}$  to 2 miles of this boning in a day. On curves the furrow is correctly super-elevated, the point under the inner rail remaining at the height of 7 inches. In this way the road is safe for construction traffic immediately after track-laying, a large amount of lifting is saved, and the extra quantity of ballast required is provided for. The section of the furrow was calculated to provide the requisite ballast for a correct lift to formation level, additional ballast being required for very low places or boxing in.

Track laying is carried out directly from the construction train which is pushed by the largest engine which it is safe to allow over the line. The material is loaded up in units of two trucks containing one-fifth of a mile of material complete. The bottom layer of rails in the rail truck rests on three or four transverse sleepers and each layer above on thin strips of packing, which is broken up as the truck is off-loaded. It is important that no bent rails or short "specials" are loaded up with the ordinary rails, as these delay the track-laying and are expensive and troublesome to pick up. The sleepers are carried from 100 to 200 yards ahead of the train and thrown down across the furrow. Here, they are roughly spaced at an even distance of 2 feet 6 inches centres by a few natives provided with gauges. This ensures the correct number being left per rail length. The centre of each sleeper is at once marked ready for the sleeper straightening and spacing party, consisting of about six natives provided with a special 90 feet chain, the links of which are exactly the length between the centres of the sleepers. This chain is stretched along the centre pegs and held by a boy at each peg, and the sleepers are accurately spaced, centred and squared to the chain by a trained head boy. It may here be mentioned that the weight of rail is 45 lbs.

per yard, and that 12 steel sleepers (weight 72 lbs.) are used for each rail length and spaced 2 feet  $6\frac{1}{2}$  inches, except at the joints, which are 2 feet  $0\frac{1}{2}$  inch.

The natives of Northern Nigeria carry all loads on their heads, and find considerable difficulty in picking up heavy weights from the ground. The work of rail carrying was, therefore, enormously expedited by the expedient of inserting short lengths of rails as cantilevers under the bottom layer of rails on the truck, and sliding the rails on to these cantilevers so that the carriers could take them directly on their heads. This expedient also avoids the tendency of rails being left behind when the construction train moves forward. The rail-carrying gangs vary from eight to ten men. For continuous work, especially when laying through deep cuttings or over high banks, it does not pay to cut down the gangs to less than ten. The number of linking in rail gangs depends on the rate desired. If over half a mile a day, a special gang lifts the rails and places them on the sleepers as near as possible in position, so that the gangs inserting the rails have less to do. The latter operation is carried out with the assistance of about six thin pointed crow-bars for each gang. The rails are next butted against the expansion irons (these are  $\frac{3}{8}$  inch thick, hot weather mid-day;  $\frac{1}{4}$  inch, hot weather morning, cool weather mid-day,  $\frac{3}{8}$  inch cool weather, morning) and fixed with two bolts. After three or four rail lengths the track is straightened to centre pegs, the sleeper spacing checked, and the train signalled forward. The remaining two fish bolts and all the keys are put in later on, sometimes two or three weeks behind rail head, though it would be better to follow close behind. Within five miles of rail head should follow the first lift party, and these leave the track accurately packed, straightened and graded at the final height of 12 inches above formation level. It will be seen that accurate pegging out, ballasting and track-laying will greatly facilitate the work of this party, who should have no difficulty in averaging half a mile a day, including boxing in, for each party consisting of one European and 150 natives. The track is then fit to run over 30 miles an hour, except over special places, such as deviations. A few small maintenance gangs should work on the section immediately behind the construction train to deal with slacks on the newly made banks, put in points and crossings, and attend to bridge approaches and deviations. During the dry weather it is possible to run over the track just as it is left by the construction train for several weeks, and it is wonderful how the line holds up under these conditions with good sand ballast. On curves, special rails 29 feet 8 inches long were used at first to keep the joints square. Owing to a shortage in these, joints on curves were staggered by starting with an 18 feet rail on the outer side just before entering on the curve, and finishing with a closer just after the end of the

curve to bring the joints square again. No time is lost cutting the closer, which is fly fished for the time being. Except for the disadvantage of the irregular spacing of sleepers, there is no doubt that the staggered joints resulted in a better running track.

The usual working hours at rail head were from 6 a.m. to 3 p.m., with an interval for breakfast at an hour depending on the progress of the work, but is possible before 10 a.m. In the hot weather in the Bako valley these hours were slightly curtailed, and work started at 5.30 in the morning. The Europeans of the construction party were accommodated in type camps from 5 to 10 miles apart, the houses being mud or grass, supplemented by tents. It is difficult to get work done on the day of changing camp, and it very often pays to reconcile oneself to losing a day or to make it fit in with pay-day. It is most important that camps should be kept thoroughly clean, and an expenditure equivalent to £1 10s. per mile was freely incurred with this object.

---

### Labour.

The labour question has hitherto been a most serious one. Some 15,000 natives were employed on the Baro-Kano Railway from January to March, 1910, and in a new country it is not easy to procure this number. Moreover, during the past season work has been carried on through large uncultivated areas, and the question of food supply has added to the difficulties. Markets were established at rail head camp, free passes were issued to traders bringing supplies to rail head, and rice was imported and issued at cost price. Weekly payments were found necessary to give confidence to the natives, and the arrangement of this, including the supply of specie from Baro, gave endless trouble.

---

### General.

A covered tool truck was kept at Railhead Camp, and saves a lot of trouble and loss in view of the frequent moves as railhead progresses. A native blacksmith and a few native carpenters are required at railhead. The latter, besides attending to miscellaneous jobs, make from local timber all the pick and hammer handles used at railhead, and also all the wooden beaters used with sand ballast in preference to the ordinary form of steel beater.

When out of touch with the European doctor, a European medical orderly is attached to railhead, and in any case a native dresser to attend to minor injuries and ailments among the labourers, which would otherwise throw a lot of extra work on the engineer in charge. A canteen truck is arranged for at railhead, through one of the Baro firms, and was found a very great convenience.

It is most important that railhead should be in good telegraphic or telephonic communication with stations behind and head-quarters. With this end the advanced telegraph station was kept pushed forward to the railway station nearest Railhead Camp. A telegraph line was laid by a construction party attached to railhead, and had no difficulty in laying two miles a day. Great trouble was experienced through breakdowns caused by lightning and by bush fires.

---

### Earth Works.

Earth works cost from £200 to £340 per mile, though, in a few places where there was very heavy work, the cost reached £800 per mile. The rate of progress has been from 15 to 26 miles per month. The cost of the work from  $3\frac{1}{2}$ d. to  $4\frac{1}{2}$ d. per cubic yard.

Rock cuttings have been carefully avoided, but heavy work has been faced to obtain a better ruling grade with a view to the best ultimate efficiency of the line.

---

### Bridging.

Bridging on the first two sections—namely up to the Kaduna—has had to be very heavy for a Pioneer line. The waterways amount to 50 lineal feet per mile on the Baro-Minna Section. The largest bridge will be about 500 feet long over the Kaduna. The largest span employed is the South African type of 100 feet. In the first section practically all the founds are in sand, and consist of wells sunk up to a depth of 20 feet. The expedient of using concrete well curbs reinforced with a few tram rails was found to be most successful. With one exception, where a powerful steam pump was used, the founds were kept clear of water by diaphragm pumps. It is vital to get all the founds in before the first heavy rains, and towards the end of the dry season the work on the piers and superstructure is practically neglected till all the founds are secured.

Steel trestle piers are used for spans up to 30 feet and can be very quickly erected. The commonest spans are 15, 20 and 30 feet. The bulk of the culverts are thick corrugated iron, 2 feet, 3 feet, 4 feet, 5 feet and 6 feet diameter the weight being relieved by dry stone walls with a concrete arch or a platform of rails and stones in the case of all culverts over 3 feet diameter. A number of thick steel culverts 6 feet diameter have also been employed.

---

### Climate.

The climate of Northern Nigeria is far healthier than that of any of the other West African Colonies, and the right type of man should have every prospect of keeping fit if he observes certain

simple precautions—namely, taking his quinine regularly; never sleeping except under a mosquito net which should be kept in perfect order; wearing mosquito boots instead of shoes in the morning and evening; always wearing a helmet between 8 a.m. and 5 p.m.; wearing a spine pad, especially during the hot weather, and not disdaining the use of an umbrella; keeping an extra blanket at the foot of his bed under the mosquito net to draw up in the cool of the morning; living temperately, and in no case touching intoxicants before sundown; taking as much exercise as possible and keeping the bowels open.

## MUNICIPAL GOVERNMENT IN THE STRAITS SETTLEMENTS.

THE Report of the Commission which enquired into the administration of municipal affairs in the Straits Settlements has, naturally enough, made a deep impression in the Colony, and has a considerable interest for other places. The establishment of municipalities in Crown Colonies represents a sort of compromise. In the large affairs the severity of autocracy is maintained, but as regards purely local matters of the kind associated with municipal activities, there is a disposition to encourage the beginnings of representative government. This is clearly sound in principle, for it is only in this way that the public can be taught to form a judgment on correct materials about public matters. There must, however, be many failures and disappointments in the process. In a population which practically has no voice in the selection of officers, and not much influence in the conduct of affairs, the difficulty of taking the first step is very great. The voters probably neither know nor care about the idea of sanitary improvement, which is the mainspring of municipal action. They show their small interest by the low number of votes, and their representatives are usually animated principally by the desire to vote against anything which costs money. In some cases the experiment has been brought to a standstill by the refusal of the council to impose any rates. At such a stage the Government must, of course, intervene, and in some way or other resume its functions; but it is advisable to keep the form of a municipal body, and to utilise as far as possible the best members of the community.

In the Straits Settlements the chances of success were at least as good as in any average Crown Colony. The population is orderly and by no means unintelligent, and there is a considerable number of Europeans. But the latter are not men of leisure. They cannot afford the time required for the examination of the mass of details which grow up. It is distasteful to them to carry out work which may at any time bring

them into conflict with persons with whom they have business or social relations. The local world is a small one, and when prosecutions have to be undertaken, as is necessary with an ignorant and apathetic population if any good is to be done, it is not surprising if the representatives show a disposition to shirk the responsibility.

Accordingly, in view of "the small interest taken in municipal matters by the general body of voters, the frequent failures to get the necessary number of votes, even when nominations take place, and the dependence on Government which is generally shown in the matter of municipal representation," the Commission recommended the appointment of a Board of Members nominated by the Governor. This throws over the principle of election by the people; but if the privilege is not valued there is no help for it. There were other reasons for the recommendations which do not make pleasant reading. It is only fair to the Municipal Commissioners to observe that the flagrant irregularities lay not with them but with the Secretariat. The assessment of houses, the very basis of municipal work, had not been properly carried out, and in some cases this could hardly have been due to mere negligence. For the general sanitary policy the Commissioners were responsible, and here the weakness of the system is apparent. It is true that much useful work has been done and that the rate of expenditure has gone up rapidly. But the good effect of the measures taken was destroyed by the ignorance and neglect of the public, and the conclusion was forced on the Commission that it was practically useless to rely on any help from it. No work has been done on a systematic scale for the suppression of malaria, and in this important matter the Straits compare badly with other tropical countries. The only remedy is to give the Government larger powers of deciding what the sanitary schemes of the municipality shall be.

A large part of the evidence is devoted to the methods of inviting tenders for stores and materials. The time allowed on these occasions did not, it was stated, permit of prices being obtained from London, and the system resulted in the local firms being able to a considerable extent to arrange matters comfortably among themselves. "It is generally decided beforehand who should get the contract, the prices being arranged so as to secure to them a satisfactory profit on the cost price, and at the end of the year the other firms interested are paid a rebate by the firm obtaining the contract." Of course, when competition is confined to specific limits, there is a direct invitation to the firms that are inside the ropes to form a pool. The Straits merchants are in no way peculiar so far as this matter goes. In days when international pools are formed in articles of necessity, it is not surprising if a small community adopts the system. The fictitiously high price which appears in the tenders is not the only irregular feature. "It is also alleged that these

tenderers quote a low price for the articles of which a few will be required, and a high price for the articles which they have the means of knowing will be used on a large scale." Of course they do : this is the regular custom under such conditions. It is, in fact, impossible to compare tenders when tenderers are only asked to put rates against articles, without being told the quantities. No one can say how the thing will work out unless he knows from other sources to some extent what quantities of each item will be required, and the local merchant does his best to find out and to adjust the prices accordingly. The only sound method is to extend the rates by multiplying them in each case with the probable quantities, and to compare the totals.

But this is a small matter compared with the evidence of corruption. "It was asserted, and documentary evidence was produced in proof of the assertion, that a commission of 10 per cent. was granted on certain bills which passed through the hands of certain officials . . . these documents were shown to the parties whose initials they were supposed to bear and the initials were admitted by them as being theirs, the reason given being that these sums were paid for working overtime and for technical advice." Certain answers amounted to this, "that it would seriously inconvenience their business to discontinue payments to municipal servants, that it was good policy to pay them . . . that in Singapore, with a few exceptions, viz., of the highest officials, the officers who insisted on getting commission were in too high a position to be attached." We do not find any evidence that any official "insisted" or in any way asked for payments, and there are no grounds for inferring corruption of this grave nature. But presents were undoubtedly given in some cases, under a colourable pretext of being for technical advice or assistance.

The Commission concluded that all articles not in the printed schedule which are produced or manufactured in Europe and America (and not locally) should be obtained through the Agent (in the United Kingdom). They also stated that having regard to certain experience of local work it would appear desirable that tenders for all large construction works involving special skill and knowledge should be invited at home and not in the Colony, and that for supervising loan works, "it would be better to engage a specially trained man for each such work." The sound principles in such matters are plain enough. The local contractor has some advantages in his knowledge of the local conditions and in his supply of labour, and he is frequently extremely useful as a sub-contractor for plain work ; but a great risk is run if he is entrusted with important work for which he has not had the proper experience and appliances. It is quite true that even with the best staffs estimates of money and time are from time to time exceeded, and

when it is difficult or impracticable to gauge the extent of a work before it is undertaken, there are likely to be troublesome questions with the contractor, as, unfortunately, the Straits are experiencing at present, but as engineering on the ground is not an exact science, all that can be done is to minimise the chance of disappointment by using the best men available. If there is enough continuous work in the Colony to qualify the appointment of a permanent official, it is, of course, wise to make one, but usually in large construction work it is cheaper and more satisfactory to send out an expert for the particular job.

The Commission conclude that the Colonial Government, as it raises the loan money required, should have some means of supervising the expenditure and securing that the money is wisely and properly spent, and recommend the creation of a composite board for this purpose.

The Commissioners have dealt ably and courageously with a trying and painful task, and left no stone unturned to get at the facts. They have been supported by the press of the Colony with excellent public spirit. "It cannot be said," the *Straits Times* wrote, "that the British have been unwilling to adopt the principle of free representative Government in their Colonies and dependencies. They have erred, if at all, in making experiments with such Government too readily. . . . The existing system stands condemned not only by reason of the deplorable corruption which has grown up under it, but by the waste of energy, the overlapping of powers, and the unsatisfactoriness of its results." This is striking language from a paper which has, with perfectly natural and proper motives, from time to time spoken on behalf of the representative system. That development is the ideal of the future; but when and where circumstances are ripe for it is another matter.

## REVIEWS AND NOTICES.

**The Broad Stone of Empire ; problems of Crown Colony Administration : with record of personal experience.**—By SIR CHARLES BRUCE, G.C.M.G. (*Macmillan & Co., Ltd.* 30s. net.)

These two volumes cover a very wide field, and the research and industry shown by their contents are remarkable. Sir Charles Bruce had a long and varied experience of the Crown Colonies, and now utilises it and the materials at his command to discuss the administrative problems connected with them. He thoroughly grasps at the outset the industrial importance of these colonies to Great Britain and the value of the various bodies which advise and assist them. He truly remarks that the employment of the white man in the United Kingdom depends, to an extent which he does not clearly realise, on the employment of the coloured man in the tropics. Every year the materials sent to this country for food, or for work, increase ; and if, as is sometimes complained, British capital is being sent abroad more and more, it may at least be urged that this is largely due to enterprise, the result of which is to feed the British market with the things that are necessary to the development of the home industries. In this matter the Crown Colonies are becoming steadily more important, and this process will surely continue.

Sir Charles Bruce deals with all the leading heads of administration, such as law, labour, health, education, religion, agriculture, forestry and defence. Any attempt to deal fully with these subjects would of course be encyclopædic. The matter given naturally reflects to a large extent the author's personal experiences, but he has displayed no little assiduity in endeavouring to complete his survey. He has also views on the question of the home methods of control. He advocates the creation of "an advisory council to assist the Secretary of State in all matters relating to the Crown Colonies." This proposal is largely based on the theory that the Colonial Office is administered by "junior clerks," a system which,

it is urged, is "deplorable, but apparently admitted." We would, with all respect, suggest that it is not admitted, and that it is not the fact. A governor who has received a despatch of an unpalatable character may occasionally have consoled himself, or others, with the theory that the objectionable criticism was really the work of a "junior clerk." But it is safe to say that no serious statement is ever sent out from the Colonial Office without the deliberate approval of a high official, and it is probable that in no other office in the United Kingdom does the Secretary of State deal so much with the work in detail. We are unable therefore to support the first advantage claimed for the proposal, viz., that the Secretary of State "will be informed of what is going on in his own office" (p. 196). Another reason is that the council would help to maintain "continuity of policy" (p. 185). The idea is that ex-governors would help to prevent this policy being changed by their successors. Very likely this would be the case, but it may be doubted whether continuity should be regarded so much as a sacred principle. In any case the existing system secures a considerable degree of continuity, and, valuable as would be the advice of a retired governor, such as Sir Charles Bruce, on a matter with which he has dealt himself, it must be admitted that circumstances are continually changing and policies with them. To follow such changes continuous work is necessary, and, if any control is to be exercised over the staffs in the colonies, it is surely better to exercise it through officials who are at work daily, than through a body which would be largely composed of officials who are presumably enjoying a well-earned rest, for the most part far from London.

We do not find in these pages any substantial evidence of such statements as the above proposal would seem to imply, and in fact Sir Charles Bruce's accounts of the measures which have been taken in the wide and varied field of administration will convey to most readers quite a different impression. Of this part of the work we have little criticism to offer. We notice that the annual average "disbursements" of the Crown Agents' Office are put at over £25,000,000 (p. 214). Some time ago the press gave prominence to a statement that these outlays amounted in one year to some £90,000,000, and manufacturers and suppliers may well wonder where these large amounts go to. The "disbursements" are in fact the total business, and are mostly loan and investment business. In the year of the £90,000,000 it was the passage of the Transvaal loan through the books, a formal matter, which produced this imposing figure. The actual purchases amount to about two and a half millions. We also observe that the Crown Agents' fund is supposed to receive the interest charged to Colonies on overdrawn accounts. Unfortunately, the interest has to be paid to the parties (sometimes another Colony which is in funds) who lend the money; the office gets nothing out

of the transaction, not even a commission. These, however, are trifling matters in so large a field, and we trust that Sir Charles Bruce will be rewarded for his labour by many readers, who will appreciate his clear style, his store of facts, and thoughtful observations on policy and practice.

---

### The Illustrated Guide to the Federated Malay States.—

EDITED BY C. W. HARRISON. (*Malay States Development Agency*:  
3s. 6d. net, leather).

In one sense Malaya has been of late prominently before this country. A great number of companies have been formed to produce rubber there, and in numerous cases the interest of the public has been demonstrated by great over-subscription. But the effect of all this on the Malayan States is hardly so considerable as might be inferred. Most of the new companies take over old coffee or rubber estates, and though of course a certain amount of development takes place, other means are necessary to supply the enterprise required for filling up the western side and breaking new ground on the eastern.

The present handbook is written to attract and guide the tourist or explorer, and begins by showing that travelling is safe and fairly comfortable. For one thing there is no "unrest" in Malaya. The labour class does not exist there, and the natives are courteous and ready to oblige. The physical features of the country are described by Mr. Harrison with a vividness which should attract the genus globe-trotter, and at the same time a good deal of information is imparted about the natural resources. The following extract deals with the fashionable industry:—

"It is a relief to find yourself amongst the rubber trees and their cool shade. Upstart cultivation though it be as compared with coconuts, rubber has made enormous strides of late years and in every district are large estates. In the burnt clearing you have left is seen the beginning of the cultivation. Here the little slim para rubber plants are planted out amongst the rotting timbers of the forest primeval. Originally sown as seed all together in a patch of cleared land they have rushed up through the soil with that endearing willingness to be good and grow quickly for which the planter loves them. At three or four feet high they are ready for transplanting, and each is carefully dug up, carried from the nursery to its prepared hole in the clearing, and left to the rapid development of a thoroughly happy tree. The rubber came originally from the other side of the world, from Paraguay in South America, but it took to Malaya at once, and had it not been that coffee was before it in Malaya, more attention would have been given it earlier. But Malaya is making up for lost time, and planting, planting, planting rubber with an almost feverish activity. The tree itself is of a picturesque habit,

leafy and very green, with a scented flower of the true tropical sweetness, adding a new but not quite a strange perfume to the innumerable sweet scents of the country. As you are not concerned with it merely as a money-maker you note the delicately pretty patterns of greyish bark splashed with patches of bright yellow mosses and decked with gleams of sunlight. But, after all, rubber is worth so much a pound, and the winning of it is interesting. So you turn to watch yet another expert. Perhaps you are by this time too late, for tapping is done in the early morning and all you see is coolies going round, emptying into large tins the bright white juice or latex from the little cups at the foot of the trees. But for your edification a tree is tapped. Estates have their fancies in knives, but probably the ordinary farrier's knife is most employed. Down the trunk of the tree runs a pattern of cuts. The knife is laid on, and slowly, carefully bearing on it, the tapper shaves off just a little slice of bark. At once the white latex oozes forth and as cut after cut is reopened the tree yields a stream of latex which runs down the backbone out to a little open spout of tin fixed into the bark near the ground. Thence it drips into a little cup, which may be a cigarette tin or some patent receptacle, or a china cup, or a coconut shell—anything indeed which is cheap and of the proper size."

Notwithstanding the discovery of other fields, the Malay States produce half the world's supply of tin, and there is plenty still left. Except on the East Coast little has been done to exploit lode or similar formations, and the explorer may find much to do.

"It is no exaggeration to say that in any part of the Federated Malay States on the West, anywhere in the thousands of acres of alluvial lands that lie at the base of the granitic hills, it would be the exception not to find a trace of tin ore in the alluvial strata. Underlying these alluvial deposits, and forming the bed-rock, are generally found on the alluvial plains, crystalline limestones, slates, schistose, or granitic rocks. In the valleys of the Kinta River, in Perak, and the Klang River in Selangor, the bedrock is mainly a crystalline limestone of commercial value. Probably one of the most unique formations in which alluvial tin ore is found is the marble cliffs that make such a striking feature in the Kinta scenery. They rise abruptly from the alluvial plains, with vertical sides, and are of the same nature as the limestone forming the bed of the valley. Whether their present exalted position is owing to volcanic action which has elevated them above the general level of the country, or whether volcanic action and metamorphism has enabled them to resist the general denudation of the other rocks, must be left to the geologist to solve. Some of these limestone cliffs are riddled with caves, and in these caves alluvial deposits of immense value have been found. Again, in many cases, these cliffs are like a bamboo structure, with a hollow core, the outer shell being of crystalline

limestone of varying thickness—the core being partially filled with alluvium highly impregnated with oxide of iron.”

The guide is well illustrated and is furnished with the indispensable map. We may mention that a station hotel will be opened at Kuala Lumpur in July next.

---

**Malta.**—Painted by VITTORIO BORON; described by F. W. RYAN. (*A. and C. Black. 7s. 6d. net.*)

Malta is, as far as any one place can be, an epitome of the successive stages of civilization. We need not lay stress on its claims to be the home of Calypso, as though her grotto in Gozo is there for anyone to see, the uncertainty of Ulysses' itinerary renders prosaic proof impracticable. But it is certain that at some such early period the Phœnicians, the foremost of barbarian nations, sailing out into the Mediterranean from the narrow strip of land that lay between Lebanon and the sea, came to Malta and occupied it for some 700 years. To the present day their rule is marked by some impressive stones, excavated in modern times, by the language, and by the characteristics of the inhabitants. To the Phœnicians succeeded the Greeks, and after them the Carthaginians. It played a part in the Punic wars and passed eventually to Rome. Under that rule occurred the event which holds the imagination of the Maltese and invests the island with a sacred character in the eyes of Christendom—the coming of St. Paul in 58 A.D. At the division of the Roman Empire, Malta was included in the Eastern half, and in the year 870 the Arabs, sweeping westward, took possession. It was so held for some two centuries when the Arabs were expelled, and then for nearly five hundred years it became a pawn in the wars of feudal lords. Eventually it fell to the Order of St. John of Jerusalem, and in 1565 underwent the “Great Siege” by the Turks. The conspicuous fortifications of the island are an indestructible monument of the rule of the military priesthood. At the outbreak of the French Revolution the Grand Master offered official condolences to the family of Louis XVI. This ended the career of the Order. Napoleon's reply was the seizure of the island, and the Knights were turned out with scant courtesy. In 1814, by the voluntary act of the inhabitants, the islands were finally vested in Great Britain.

From the first the difficulties of British administration were very great. The laws, customs and ideas of the inhabitants were wholly strange to the first governors. In recent years there has been much friction over the language and marriage questions. But on the whole, considering the wide differences between the two races, things have gone on with a remarkable degree of freedom from

serious trouble. The indigenous and exotic societies are as much apart as ever, and there is little social mingling. Each has its own ways and they do not blend. But despite some awkward incidents, such as almost inevitably arise from fundamental differences, the general spirit is one of loyalty on the one side and respect on the other. The political disputes are not perhaps so important, or excite so much feeling, as may appear on the surface. The Maltese are a light-hearted race and their Islands afford abundant attractions. It is of course well known socially to the military world, but the ordinary winter tourist is not as much in evidence as he should be. The limited hotel accommodation has something to do with this, but this would no doubt soon be rectified if more patronage were forthcoming. The present volume is excellently adapted to excite a wider interest in the place. The historical account and the description of the places of interest are vividly done, and the illustrations are numerous and captivating.

---

**Letters and Sketches from Northern Nigeria.**—By MARTIN S. KISCH, Assistant-Resident, with an Introduction by Sir PERCY GIROUARD, and numerous Illustrations by the Author. (*Chatto & Windus. 6s. net.*)

The Colonial service lost a most promising recruit when Mr. Kisch died of diphtheria after a few months' service in Northern Nigeria. Sir Percy Girouard says: "My personal acquaintance with him and his work was brief, but of sufficient duration to predict a brilliant future had he been spared. His early mastery of languages, his unflinching good humour and camaraderie, and his high mental gifts, would have placed him anywhere in the Nigerian Service." Diphtheria is almost unknown in Northern Nigeria, and its origin in this instance could not be traced.

The letters abound with allusions to the men whom the writer met and whose identity can in many cases be easily detected by the initial given, to say nothing of the lively sketch which usually accompanies it. But there is only the spirit of good-fellowship in these references, and no one's feelings will be hurt, though naturally things are given a turn of humour, as when the first "old coaster" met is described as about 5 feet 11 inches high, and 10 feet 11 inches round the equator, and a military officer is mentioned as having a glass eye which was so good that it rolled a little and had far more expression in it than the other optic. The journey out from Liverpool and up to Sokoto is described with the vivid detail of a clever writer who meant to tell his people exactly what he was going through, though naturally the style is of a domestic character and there is no attempt to get below the surface of things. Everything is illustrated

with an amusing sketch. The following extract shows the sort of work which may fall to the lot of the young official just arrived:—

“I have to take over the whole Provincial Office work on Tuesday, which means taking charge of £7,000 in the safe: collecting and counting £23,000 from the Sarikis; paying everybody; ordering carriers or donkeys; sending in countless returns every month, quarter, and six months; hearing cases in the Provincial Court, of which I am a judge; taking a record of all cases in the native courts; copying maps; measuring prisoners on arrival, and entering particulars in six different books; estimating the price for guinea-corn; and ordering any building necessary to be built, and paying for it. Yesterday there were 1,000 carriers, all in one tremendous string, in front of my office for me to inspect their loads of corn. I have to inspect 4,000 more loads. I have four messengers and an interpreter, all tremendous “bloods” who ride horses and wear enormous turbans and beautifully embroidered trousers and rigas.”

#### Imperial Institute.

The report for 1909, issued last October, contains an account of minerals collected in Southern Nigeria. Lignite has been found of good quality and suitable for use as fuel and for the production of gas. In Northern Nigeria there are immense deposits, favourably suited for export, of iron ores of good quality. Limestone has been collected between Jakura and Wa and should be a valuable article in West Africa. Large quantities of pegmonite carrying tinstone easily workable, were found in the Eri district. In Nyasaland a fine quality of flake graphite has been received from Mkoma, and this discovery will attract attention. Promising samples of asbestos have been received from Cyprus.

#### Ceylon Mineral Survey. (Cd. 5390).

This report shows that the island contains, in addition to gem stones, a number of minerals of commercial importance, of which only graphite, mica, and thorianite are at present worked. There is room for more enterprise as regards mica. Thorianite is a new mineral only so far found in Ceylon, and is used as a source of the thoria in incandescent gas mantles. This mineral will no doubt be in increased demand and should attract further exploration.

The Report on Nyasaland for 1909–1910 contains a very encouraging account of cotton prospects in the Protectorate:—

“The cotton crop has been successful and is rapidly improving its already strong position.

“The European acreage under cotton has increased from 6,037 last year to 8,975 for the year under review, while the crop at present being harvested covers over 12,000 acres. The European

output for the year 1909 amounted to 852½ tons (unginned). A particularly gratifying feature is the increasing yield per acre. Many estates which produced 100 lbs. of lint per acre a few years ago, are now averaging as high as 165 lbs., while some gardens have yielded over two hundredweight. As to quality, the highland grown cotton is superior to that produced on the lower levels, although the yield of the latter is generally heavier. Nyasaland Upland cotton in point of lustre, silkiness, and length of staple, leaves practically nothing to be desired, and at its best is unrivalled. It has obtained the record price of 1s. 2½d. per lb., and the brokers have given it as their opinion that the Nyasaland Upland crop of 1909 is the finest cotton ever grown from Upland seed in any part of the world. This excellent variety is now thoroughly acclimatised here and is doing very well over an unusually wide range of altitude namely, from 1,000 to 3,000 feet. The European-grown Egyptian cotton on the Lower Shire River was a partial failure, owing to the ravages of bacterial blight, an American disease. However, although the crop was small, it sold at prices which compare favourably with those of cotton grown in Egypt.

“The native cotton industry has likewise made satisfactory progress. If an important export trade in cotton is to be created here, it is imperative that the interest of the natives should be aroused and their willing co-operation enlisted. The constitutional apathy of the local tribes towards all novel forms of industry seemed at one time to present an almost insuperable obstacle to the establishment of cotton as a general staple of native cultivation. It may even yet be too soon to indulge in too sanguine predictions, or to assume that cotton will eventually take its place in every village garden and obtain a fair share of the attention which is now given to cereals, such as maize and millet. This, however, is the object which the Protectorate Government has in view. Its accomplishment must necessarily be a gradual process, because if the co-operation of natives is to be of any real and lasting value, it must be given freely and intelligently from a conviction of the benefits which it confers on the cultivators themselves rather than from any unreasoning acquiescence in the wishes of those in authority. There can be no doubt that very encouraging progress has already been made towards this end. The native cotton crop for the year under review amounted to 220 tons, an increase of 130 tons on the previous year. The crop now approaching maturity promises well, and, as seed distribution has practically doubled in amount, there is reason to anticipate a further large increase in the output.

“The quality of native-grown Nyasaland Upland cotton has always been as good as, if not better than, European-grown Upland, but the native-grown Egyptian crop has in the past been very disappointing. A marked improvement has, however,

resulted from teaching the natives how to grade their cotton, and a large proportion of the native crop from Port Herald, on the Lower Shire River, obtained 1s. 1d. per lb., one of the highest prices hitherto secured by Egyptian cotton in this Protectorate. Under the system at present in vogue natives grow and sell their cotton more or less under the auspices of the Resident of the district, who, while leaving the vendors a perfectly free choice as to the disposal of their produce, assists them in every possible way by seed distribution, by advice as to methods of cultivation and otherwise. It is interesting to note that not a few natives are now opening up independent plantations of their own, apart from the ordinary village gardens, where the cotton is tended jointly, and the profits are divided as a sort of communal enterprise.

“In course of time it is to be hoped that native planters will be able to reap the benefit of any rise in the value of raw cotton, but at present there is much to be said in favour of adhering to a fixed purchase price, since the native mind is not yet competent to grasp the idea of market fluctuations and would be inordinately puzzled and discouraged by any sudden depreciation in the value of his wares.”

---

We have received the first number of *The Round Table*, a new quarterly periodical which will be concerned solely with Imperial affairs. The place of honour is given to an article on Anglo-German rivalry, and, under the head of British politics, “The Constitutional Crisis and “The Revival of Home Rule” are discussed in articles, which have inevitably lost something of their actuality in consequence of the political developments which have occurred since they were written. Canadian and South African affairs are dealt with by local correspondents, and in future issues it is intended that other parts of the Empire shall receive similar treatment. The papers in the first number reach an unusually high level of ability, and the attempt to avoid partizanship and sectional bias has met with a considerable measure of success. The price of *The Round Table* is 2s. 6d. a copy, or 10s. per annum, post free, and it may be obtained from The Secretary, 175, Piccadilly, W. ; A. J. Glazebrook, Esquire, James Buildings, Yonge Street, Toronto ; J. Tyndall, Esquire, 29, Sauers Buildings, Johannesburg ; and J. A. Atkinson, Esq., 162, Featherstone Road, Wellington, N.Z.

---

The November number of *Travel and Exploration* contains an article on Bermuda as a resort for tourists. The claims upon this fortunate class are continually increasing in number, but, certainly, Bermuda has special attractions as a “winter paradise.” Amongst them may, perhaps, be numbered the fact that there are no railways, tramways, horse cars or motor cars.

**BUSINESS NOTES.****Oil.**

The great rush of capital to the Russian oil fields has no doubt checked developments in our own possessions. Probably the Russian boom would have come earlier but for paucity of suitable shipping, and the heavy dues on oil through the Suez Canal. The Texas developments seriously affect the position of the big American trust, and the action of this body in reducing rates abroad, which was forced upon them by increasing competition, tends further to put off exploration. For export purposes the good distribution, the elaborate steamship and barge service, and the wide business ramifications of that body will be powerful weapons. Meantime the use of liquid fuel is spreading in all directions, not only in marine engineering, but in power stations, locomotives and metallurgical processes. The most striking recent improvement is that of the Diesel Engine Company in producing a marine engine which is coupled direct to the propeller shaft without the intervention of a clutch. The engine itself is reversible and variable in speed. It is said that a vessel so fitted, running nine knots an hour, with an engine of 500-h.p., could cover 2,000 miles with 25 tons of fuel, costing about £52. The Lloyd's report, lately issued (1909-1910), contains the following remarks on the subject :—

“The use of internal combustion engines for marine purposes has hitherto been confined to small vessels and yachts, but the possibility of the use of this description of engine as the motive power of large vessels is now becoming a question of immediate and practical importance.

“The internal combustion engines in most general use on land and also those fitted in small vessels are worked upon the 4-stroke cycle principle, and are single-acting, so that with each cylinder there is only one impulse for two revolutions of the shaft. With this type of engine there is considerable difficulty in effecting the reversal of the direction of rotation of the engine, and

when these engines are used for marine purposes the astern motion of the screw has usually been obtained by the use of toothed wheel gearing.

“Comparatively recently there has been a development in the Diesel Oil Engine for marine work. A 2-stroke cycle has been successfully adopted, and the reversal is effected in the engine itself, the crank shaft being directly coupled to the screw shaft. The Diesel Oil Engine is now being fitted to three fairly large vessels being built on the Continent under the supervision of the Surveyors to Lloyd’s Register. One set is being constructed on the older principle of the 4-stroke cycle with single-acting cylinders, and will be of about 450 i.h.p. Another set is being made on the 2-stroke cycle, also single-acting, and is intended for a twin-screw vessel, the power being about 900 i.h.p. on each shaft. The third set is being made on the 2-stroke cycle double-acting system, each cylinder providing two impulses per revolution; this also will be fitted in a twin-screw vessel, the total power being about 1,800 i.h.p. In each of these cases the engines will be directly coupled to the screw shafts.

“In a set of internal combustion engines, which is being constructed under the Society’s survey in this country for a vessel of about 260 tons, there are several novel features. The engines are intended to work with gas produced on board from anthracite coal. The cylinders are of comparatively small size, and the engines are intended to run at a high rate of revolution, and will not be reversible. The connection with the screw shaft will be made by means of a hydrodynamic transformer in which a turbine pump driven by the engine delivers water to another turbine coupled directly to the screw shaft. The arrangement is such that the screw shaft will rotate at a much less rate of speed than the engines, and provision is also made for reversing its direction of rotation.

“The experience which will be obtained from these four applications of the internal combustion engine is being looked forward to with great interest and will provide data of extreme value.”

The Trinidad Government have decided to institute a licence authorising applicants to examine or explore the surface of any Crown lands or other lands on which the Crown has oil and mineral rights, with the object of selecting areas over which to apply for prospecting licences. These exploration licences will carry no obligations other than a deposit of £2 with the application. The licence may be made an exclusive one; but this would only be done in the case of companies of the highest standing, financially and technically. Such a licence has been approved to the British and Foreign Oil and Rubber Trust over lands totalling some 47,000 acres.

It is a great convenience to a Colonial Government if there is a leading company which can act as a common carrier and make other arrangements which benefit the whole trade. Thus in Burmah the Burmah Oil Company is bound by its agreement with the Secretary of State to place 20 per cent. of the carrying capacity of its pipe at the disposal of other persons in the business, and to maintain large tanks for the reception of oil brought in by outside producers. The Trinidad Government have a similar object in view.

West Africa has so far been disappointing; the geological formations are favourable, and there are numerous patches of bitumen; all that is wanted is the oil.

Mineral oil springs have been discovered in Newfoundland, and one company is at work on them. Each year, in fact, tends to confirm the opinion that the mineral resources of this near colony deserve better attention than they have received. There are extensive formations of asbestos and chromite which await development. Mining leases are granted on easy terms. The Harmsworth Company have been very successful in the introduction of paper, and there is room for much further enterprise.

---

### Tin.

In Nigeria the prospects are good, and a great number of prospectors are at work. A "Mineral Proclamation" has been issued in Northern Nigeria; the fee for a "prospecting right" is £5, and for an exclusive licence to prospect, £50 per square mile. Mining leases are only granted on proof of the possession of sufficient working capital (which has been put at £500 per square mile), and on various terms according to kind; a royalty of £5 per cent. is imposed on all metal won under mining leases. We observe that all mining areas extend "downwards to an unlimited depth from the surface:" it is to be hoped that full advantage will be taken of this liberal permission.

---

### Other Products.

The fall in the market price of rubber has not materially affected the activity of producers. Many calculations as to the future price seem to be based on the assumption that all the new plantations will secure a good yield from all their trees and for a long time: in practice the yield is very variable, and this must be taken into account.

Sugar, after the heavy fall, is likely to show a more regular level, but no product is more uncertain in price, partly because it is the subject of extensive gambling which causes artificial variation.

profit, the cost of a ton of fibre is materially reduced, and with cheaper means of transport, this branch will be reduced by one-half its present cost. With the present hydraulic press it costs us about 6d. a bale to bale, cover, and mark the bales. It is a very slow process, as only five bales per day are turned out with this machine, as against six bales with the old hand press, which cost about £30 as against £200 for the hydraulic machine. If a lever press as supplied by Roberts, of Liverpool, with four additional boxes, were installed later, we should be able to turn out between 20 and 25 bales per day, at a cost of, say, 3d. a bale. Roberts' press costs about £60 to £70 more than the press obtained from Pynegar, and it would soon pay for itself by giving larger and cheaper returns. You will see that, taking the larger cost which is incurred by buying native leaves £8. 10s. 5d. a ton, American, of fibre delivered into New York, there is a very large margin of profit, even at the low price of £23 to £34 obtained in New York at the present moment."

---

Wanganui, New Zealand, boasts a well equipped fire brigade, and claims the distinction of having been the first Australasian town to adopt self-propelled fire apparatus. A steam-driven motor fire engine has been in satisfactory service for over seven years, and has now been supplemented by a petrol motor first-aid machine, comprising a hose tender, ladder carriage, hose reel and chemical engine. This will be used for first turn-out to a fire, and as it can start instantly, and travel at between 20 and 30 miles an hour, it should prove of immense value; in fact, there is no doubt that a large number of fires will be extinguished by the chemical engine alone, without resort to more powerful pumping plant. The chemical cylinder contains 33 gallons of fire extinguishing fluid, and can be brought into action in a few seconds. The ladders, which can be used for life-saving, or as a means for gaining access to the flames, extend to 30 feet, and can be rapidly unshipped from the carriage when required. Both the new motor and the old are productions of Messrs. Merryweather & Sons, of London, who, in the course of the last ten years, have built over 150 fire brigade motor vehicles, and have recently been appointed fire engine makers to His Majesty King George V.

---

#### Trinidad Floating Dock.

This dock was taken over by the Government in May, and it was an interesting question whether any better results would be obtained under such management than the company had been able to show. So far there are clear indications that this will be the case. A clientèle is being steadily built up, and the result of the first four months' working showed a surplus of receipts

over expenditure of about £300. This certainly means that officials can compare favourably with a private company in zeal and efficiency.

---

### Motor Boats.

The fitting of auxiliary motors is, as was to be expected, greatly increasing, especially for vessels which have to manœuvre in narrow waters. A very successful instance was shown at Cowes, in the new schooner yacht "Sylvana" of Col. Courtenay Morgan, which threaded the lines of the assembled yachts with remarkable ease. The installation is a 47 b.h.p. Thornycroft oil engine, four cylinders, transmitting the power through a reversing gear of special construction to a three-bladed propeller revolving at 350 revolutions.

---

### Water Turbines.

The scientific treatment of this subject is inadequate in this country, and German treatises have to be resorted to for the best information. Messrs. Raithby Lawrence & Co. have brought out a well got-up work by Mr. Jens Orten-Böving (10s. 6d. net.), which deals fully and clearly with the modern theory, designs and application of water turbines. The work should be of practical use to those responsible for such installations.

---

### Reinforced Concrete.

*Concrete*, in its October number, discusses the report of the Special Committee of the Institution of Civil Engineers, and gives an account of the system used in the imposing "Wesleyan Hall," which is arising in Westminster. On this building Kahn bars are employed.

## RAILWAY NOTES.

### Ceylon.

There was a very satisfactory increase of revenue in 1909, all the staple products showing development, especially rubber. The increase naturally caused some congestion, and the works which are in progress added to the embarrassment; thus the staff had many difficulties and may be congratulated on the results.

On the Ratnapura extension, by the end of June last, for the first nine miles the earthwork and masonry were complete except at a few points, and were in a forward state for a further nine miles. The permanent way was laid for five miles. The work appears to have been done within the estimate.

The Colombo Station extensions were about three-quarters finished.

On the sea-coast duplication and Ragama widening, the work generally made fair progress during the first half of 1910, the earthwork and bridges and culverts to the north of Colombo being well advanced, and south of Colombo as far as Wellawatta, the work was about half finished, and at rates closely approximating to the estimates.

The Negombo railway, which was opened on 1st December, 1909, was completed well within the estimate, though in some respects expenditure was incurred which had not been contemplated. This result is largely due to the good work of Mr. Bowen and his staff.

---

### Federated Malay States.

The profit on the open lines in 1909 amounted to a dividend of 3.18 per cent., a slight falling off from the previous year, and the motor service is not a financial success. There has been a serious falling off in the carriage of live stock, which is probably due to the system of cold storage. On the Johore State Railway there was a loss of \$50,259.38.

**Straits Settlement.**

It is contemplated to complete the Penang Hill railway, which would thus render possible a settlement on the high levels, which would be a health resort for the whole of the Malay States.

---

**Mauritius.**

A loan of £270,000 has been authorised for the renovation of the railways, which is urgently needed.

---

**Kowloon-Canton.**

The British section was opened for passengers on the 1st October last. The history of this railway has been a chequered one. The concession for it was obtained in 1898 by a private company, but this body was so exceedingly slow to set to work that the Colonial Government took over the British section. This was done with dramatic effect. The loan bill provided not only for the cost of the Hong Kong section, but for "other purposes," and it soon became known that this meant a loan to the Chinese to enable them to buy out the American and Belgian interests, and to construct the Hankow-Canton section themselves.

The original estimate has been considerably exceeded owing to the exceedingly hard rock encountered in the Beacon Hill tunnel. This excess, and the faults of some of the bridges, to which we have previously referred, have caused a good deal of criticism, but, on the other hand, the Chief Engineer of the Chinese section states that the British section is a "lasting monument to British engineering," and the General Manager considers that the cost compares favourably with that of similar work elsewhere.

The line will, no doubt, introduce a new element into the social arrangements of Hong Kong. "All of us," observed Sir H. May at the opening, "Europeans and Chinese alike, have a feeling while resident in Hong Kong, akin to what the now historic Kowloon tiger would feel if he were caged. We want more elbow room. We need more frequent change of environment. This railway will enable some of us to take short holidays from our work—and from each other."

Thirty miles of the Chinese section of the Canton-Kowloon railway have been opened, and it is expected that the through communication will be established by June next.

---

**Uganda.**

It is contemplated that the Magadi branch shall start from the main line at mile 282, and the ruling gradients will be 1.5 per cent. to 2.5 per cent., compensated with 10° curves. Steel sleepers will be used throughout.

The soda ash to be carried will weigh about 62 lbs. per cubic foot, or 36 cubic feet to the ton. The "Mallett" type of engine is considered suitable for the purpose, with 9.5 to 10 ton axle-loads.

---

### Lagos.

Record floods occurred in August in the Kaduna River, and the work was, consequently, retarded. The girder material, which had been forwarded to Minna, was therefore returned to Baro, and taken up the Kaduna and over the Barijiko-Zungern tramway. The delay is regrettable, but the heavy wash-outs on the Link line made it unavoidable.

Railway at that date remained at the Mutu River, as it was thought best to allow the new banks to settle, and to get on with the earthworks ahead before continuing the platelaying. The programme contemplated completion to the Igberi River by the end of the year.

The Niger Bridge, North Channel, will be open about the end of January.

The half-year ending 30th June last, showed a great increase of revenue on the Lagos Railway, the revenue being £127,825 as against £95,117 in 1909. This result was practically due to palm kernels.

---

### Lagos Harbour Works.

The Secretary of State has authorised the carrying out of the whole of the contemplated works continuously to completion. It is desirable to hasten the progress of the Mole works as quickly as possible. The difficulty is the supply of labour at the quarry, the work being comparatively severe, but an extra rate of pay may overcome this. The works to be carried out are those recommended by Messrs. Coode, Son and Matthews in their report of 1898, which has been published.

An interesting feature of the work done is that the westerly line of breakers has receded about 700 feet.

---

### Gold Coast.

The revenue for 1909 showed a good increase, and is the largest ever earned. There was a marked activity in the mining industry which enhanced the spending powers of the population, and benefited the trading firms. Native timber was the only backward item. The output of gold decreased, but this was chiefly due to the suspension of crushing to allow of development work and new plant.

**Accra-Akwapim.**

The damage done by the flood was, no doubt, due to insufficient openings, and the only remedy is to build extra openings. Instructions have been given for this, and the banks and bridges will be raised at places. The line suffered very severely owing to the water being banked up against it, and prevented from flowing away. Such floods are most dangerous when subsiding, as the water appears then to have a power of suction. The line was laid on low-lying ground, apparently to avoid cutting and comparatively heavy gradients; but it is clear that this policy is expensive, ultimately, if there is a possibility of floods.

A working survey is in hand from Mangoase to Komfrodna. Reconnaissance surveys will be made of the two routes recommended by the Accra Chamber of Commerce and the West African Chamber of Mines respectively.

---

**Tarquah-Prestea.**

By August the rails were carried into Broomassie, and it became possible to deal with some of the mines traffic. The open road, where the ballasting was completed, was being maintained in a very satisfactory manner. The Ancobra bridge was nearly finished. The bridging of the Ancobra and Hurri Rivers was carried out against unusual difficulties, and both structures are striking examples of engineering skill.

The delay in completing the branch railway has, no doubt, caused much inconvenience to the mining companies, which were expecting an earlier date; but the first locomotive passed Ancobra Bridge on the 5th November. The works beyond had been completed. The work could have been finished earlier, but only by the simultaneous construction of all the heavy bridges, and this would have necessitated the carriage of material on the natives' heads. The construction of the siding has recently been stopped for want of money.

---

**Sierra Leone.**

It has been decided to continue the railway from the present terminus near Yonni to Rowalla, a distance of about 50 miles. It will be constructed by Mr. F. A. Target. It is expected to be completed by the end of 1912, and at a cost within £130,000.

The results of 1909 continue to show an improvement, but they do not furnish any immediate prospect that the line will contribute, otherwise than indirectly, to the interest on its capital cost. This would be altered if the sources of traffic are increased by the extension to productive areas.

**Gambia.**

A further expenditure on the Kai-Hai Channel Dredging Works has been approved, on the understanding that, if vessels of 15 feet draught can pass, the shippers of ground nuts are prepared to pay an extra shilling export duty per ton. This is an interesting case of a sort of bargain between Government and public for payment by results.

A survey by an officer of the Royal Navy is contemplated of the part of the Gambia River between Tendaba and McCarthy Island.

---

A considerable area of "Wunderlich" patent stamped steel sheeting has been used in the new Colombo buildings for ceilings and dados, with a very pleasing effect.

---

In these days of competition by railways for the patronage of tourists and sportsmen, much thought is given to the ways and means by which the attention of these fortunate and presumably moneyed classes can be drawn to a particular country and road. Perhaps few people would guess what organ of public opinion proved in a recent much advertised case to be the best medium abroad. It was *Punch*, and quite rightly.

## MEDICAL NOTES.

### Sleeping Sickness.

The *Bulletin* of the Sleeping Sickness Bureau (Vol. II., No. 20) gives full particulars of fifty recorded cases of sleeping sickness in Europeans, from which we extract the following particulars:—

*Sexes.*—Of the 50, 45 were men and five women.

*Occupation.*—Their occupations were as follows:—

Missionaries	...	...	...	...	11
Traders	...	...	...	...	6
Planters, &c.	...	...	...	...	6
In military employment	...	...	...	...	6
Employed on river steamers	...	...	...	...	5
Engineers	...	...	...	...	3
Doctor	...	...	...	...	1
Not stated	...	...	...	...	12
					<hr/> 50

*Place of infection.*—As far as the places of infection can be ascertained they were:—

Belgian Congo	...	...	...	...	19
French Congo	...	...	...	...	14
Uganda	...	...	...	...	4
Angola	...	...	...	...	3
Island of Principe	...	...	...	...	3
Gambia	...	...	...	...	2
Cameroons	...	...	...	...	1
Katanga	...	...	...	...	1
Nigeria	...	...	...	...	1
Sierra Leone or Gold Coast	...	...	...	...	1
Fernando Po or Gold Coast	...	...	...	...	1
					<hr/> 50

“*Result.*—Of the 50 patients, 30 are known to be dead, 11 survive, and the fate of the remaining nine is uncertain. Of the 30, 14 lived a year or more after trypanosomes were discovered, and four, two years or more. Of these, one lived three and a quarter years and one (Case 10) six years.

“The fact that of 30 patients who died, four only survived more than two years after the disease was diagnosed, suggests that in cases which have exceeded this duration there is good hope of ultimate recovery. Case 10 appears to be quite exceptional. It seems safe to consider Case 6 to have made a real recovery, and if we admit this, there are grounds for hope that Cases 11, 19, 21 and 22, if not others, have done the like. No attempt has been made in this analysis to consider the treatment in any detail, but it may be noted that these early cases were variously treated, and in no instance with the large doses which are given nowadays. Their recovery may be attributed to the resisting power of the human organism at least as much as to the treatment. It is possible, however, that they were mild cases, and that energetic treatment, not needed for them, was necessary to save any of the 30 persons who died.”

We have also received Nos. 21 and 22 of the *Bulletin*.

### Yellow Fever in West Africa.

As a result of the enquiries which he undertook during his recent mission to West Africa, Sir Rubert Boyce has come to the conclusion that yellow fever is an endemic disease on the West Coast. Should this opinion be definitely substantiated, it marks a discovery of first-rate importance. Sir Rubert Boyce is the last man to desire that his theory should be accepted without the closest scrutiny, but the arguments with which he supports his case are exceedingly weighty. At first sight, such a discovery might seem to give ground for serious alarm, in view of the terrible reputation of the disease, and its peculiar deadliness to newcomers from temperate climates. But if Sir Rubert Boyce's view is correct, it will only mean that a danger always existent, but hitherto unrecognised, has at last been fully understood; and, thanks to the recent advances in the science of tropical medicine, yellow fever may now be regarded as a disease which can be controlled and stamped out with comparative ease, so soon as it is recognised. In fact, should it be determined that many of the severer forms of “fever” long prevalent in West Africa are true yellow fever, we may look forward with confidence to their eradication at an early date, and the discovery may prove to be the starting point of a great improvement in health conditions on the West Coast.

**Entomological Research.**

It will be remembered that in June, 1909, the Secretary of State for the Colonies appointed an Entomological Research Committee, under the Chairmanship of the Earl of Cromer, with the especial object of furthering the study of economic entomology, and primarily of the part played by biting flies in the dissemination of human and animal disease in tropical Africa. Under the auspices of this committee a *Bulletin* of Entomological Research is published, of which three numbers have already appeared. The articles printed in the third number show how wide is the field of research covered; the insects dealt with being responsible for diseases in plants, as well as in human beings and animals. Mr. Guy A. K. Marshall is Scientific Secretary to the Committee, and copies of the *Bulletin* (price 3s. each) may be obtained from Messrs. Longmans, Green & Co., 39, Paternoster Row, E.C., and Messrs. Taylor and Francis, Red Lion Court, Fleet Street, E.C. It is very desirable that this publication should become widely known in all tropical regions.

**Anthrax.**

Professor Annett, of the University of Liverpool, has recently elaborated a quick and certain method of diagnosis which does not rely entirely on the microscopical examination of stained specimens, but involves the use of an incubator, petrie dishes and Agar culture tubes. It is extremely simple, and furnishes, it is claimed, absolutely certain diagnosis in three hours. The apparatus costs about £40.

**Plague.**

The Lister Institute hope to bring out shortly an improved anti-plague serum, and will, no doubt, be prepared to supply samples for trial.

Professor Ronald Ross has published a little book ("Philosophics," Murray, 1s. net), which must, we think, be unique in character. It is a collection of verse expressing the moral or poetical side of a medical man's experiences. There is a striking elevation of thought and diction throughout, and the semi-professional treatment of subjects gives the poems a serious interest:—

"The painful faces ask, 'can we not cure?'

We answer, 'no, not yet'; we seek the laws.

O God, reveal thro' all this thing obscure

The unseen, small, but million-murdering cause."

## COLONIAL STAMPS.

In view of the necessity for an early decision, as to any changes which the various Colonies may wish to make in their issues of stamps in consequence of the accession of H.M. King George V., it may be of interest if we recapitulate shortly the courses which are open and explain their several advantages.

The majority of the Colonies, which have stamps carrying the King's head as the central portion of the design, make use of one or more of the general keyplates for which no charge is made, having already purchased border or duty plates to fit the keyplate.

The four keyplates may be for clearness divided into two divisions:—

(A) The keyplate used by Sierra Leone, Seychelles, etc. This carries not only the King's head, but also either the word—(1) "Postage" on each side, (2) "Revenue" on each side, or (3) "Postage" on one side and "& Revenue" on the other. These are three distinct keyplates, each of which is fitted by the plate bearing only the name of the Colony and the value. The advantage of using this keyplate is that either of the three kinds of keyplates can be used at will with one set of duty plates, producing postage stamps, revenue stamps, or stamps for both purposes. Thus Sierra Leone uses the double purpose stamps, whereas Seychelles has two distinct series. The latter plan naturally facilitates the discrimination between revenue from postal and fiscal sources, but is not so convenient to the users.

(B) The keyplate, which has been comparatively recently introduced, carrying the King's head alone in an oval, the name of the Colony, the value and the use to which the stamp can be put being supplied from the border plate, *e.g.*, the Nyasaland Protectorate stamps. The appearance of stamps printed from this keyplate is very much the finer, but, as the purpose for which the stamps may be used is indicated in the border plate, unless so-called "unified" or double purpose stamps are required or stamps for one purpose only, it is necessary to have two sets of border plates,—one for postage and the other for revenue stamps.

There are, however, certain Colonies, such as Ceylon, which purchase their own keyplate as well as border plates. On the present occasion such Colonies will have to decide between buying a fresh keyplate or a set of border plates for use with one or other of the general keyplates. Where the number of values required is comparatively small, the latter course would be the less expensive, as, in buying a new keyplate, it is necessary also to contribute to the cost of the original King's head die from which the special keyplate is made.

The remaining Colonies which use stamps carrying the King's head are the Falkland Islands and the Turks Islands. In both cases the head, unfortunately, appears without a crown. They are printed by the copper plate process, which is decidedly more expensive than the surface process, and at one operation, so that a complete set of new plates will be required.

Colonies which have adopted their own badge or arms as the design of their stamps, can, at a very small cost, show the King's head on a certain number of values, as Mauritius does, by ordering duty plates for some values to fit one of the universal keyplates.

The disadvantage of a Colony using its own keyplate of the King's head design is apparent at the present moment from the necessity of having a new one made instead of using one which is supplied gratuitously. Colonies which use the universal keyplate will be put to no expense by the present change.

BRITISH SOLOMON ISLANDS PROTECTORATE.—4d. stamps have been despatched.

BRUNEI.—\$5 and \$25 stamps have been supplied for the first time. The colours are those appropriated to the 10s. and £1 values respectively, there being no colour appropriated on the colour scheme to any value between £1 and £5.

CEYLON.—2 cents and 3 cents stamps have been supplied, the former in a slightly different shade, the latter in the same colour as before, but showing the value in solid figures on a white ground.

FEDERATED MALAY STATES.—Another of the three States on the Eastern side of the Malay Peninsula, which came under British protection in July, 1909, *i.e.*, Kelantan, has now been supplied with a set of stamps of the following values:—1, 3, 4, 5, 8, 10, 30 and 50 cents, and 1, 2, 5 and 25 dollars. They have been printed by the keyplate system and the surface process; the first six being on unaur-

faced and the last six on surfaced paper. The colours of the stamps follow the Federated Malay States series, value for value, with the exception of the 30 cents stamp, which is substituted for the 20 cents stamp, and is printed with purple centre and red border.

GIBRALTAR has received a supply of 8s. stamps in the new colours.

GILBERT AND ELLICE ISLANDS PROTECTORATE has now been provided with a series of stamps showing a representation of a Pandanus tree or Screw pine. The values are the same as those which we reported in our last issue, and the colours are those of the colour scheme designed for steel-plate stamps, by which process they have been produced.

JAMAICA has now been supplied with a 2d. stamp printed from the new Universal keyplate, *i.e.*, that showing the late King's head in an oval.

NEW HEBRIDES (Condominium).— $\frac{1}{2}$ d., 1d., 1s., 2s. and 5s. stamps and 5 and 10 cents., 1, 2 and 5 francs have been despatched, the former to the New Hebrides and the latter to Paris, whence they will be consigned as required to the islands, and where they will be on sale to the public at the Agence Comptable des timbres poste Coloniaux, 36, rue Vaneau. The colours of both sets of stamps correspond as far as possible with the copper-plate colour scheme, but where they diverge in value different colours are given to the French stamps. These values will shortly be followed by 2d.,  $2\frac{1}{2}$ d., 5d., 6d., and 20, 25, 50 and 75 centimes. The colours decided upon for 75 centimes is orange on white paper; 1 franc, red on blue paper; 2 francs, purple on white paper; and 5 francs, red on green paper.

ST. LUCIA.—6d. stamps have been despatched, the value being now indicated in the colour assigned to it in the new colour scheme.

STRAITS SETTLEMENTS.—A new \$25 stamp has been supplied, printed in purple on blue surfaced paper.

SOMALILAND PROTECTORATE.—3, 4, 6 and 8 annas stamps have been supplied for the first time on surfaced paper, which also for the first time bears the multiple watermark.

---

The stamps of Jamaica, which form the subject of the latest Melville Stamp Book, have a special unity, in that they have all been printed by one firm, and 1910 marks the fifteenth anniversary of the first issue of stamps by the Colony. Incidentally, it is curious to notice that, in several cases, the original designs have been adhered to till the present day. The book, like its predecessors in the series, leaves nothing to be desired in style or matter. It is abundantly illustrated and a wonderful production for the price.

A second edition of "Great Britain : Line Engraved Stamps," in the same series, has also reached us.

The Melville Stamp Books, "Jamaica " and " Great Britain : Line Engraved Stamps, 2nd Edition " 6d. net ; published at 47, Strand.

---

**RECENT TRANSFERS AND PROMOTIONS  
MADE BY THE SECRETARY OF STATE.**

- SIR ARTHUR YOUNG, K.C.M.G. (Colonial Secretary, Straits), Chief Secretary, Federated Malay States.
- Mr. E. L. BROCKMAN, C.M.G. (British Resident, Negri Sembilan, Federated Malay States), Colonial Secretary, Straits.

# FORTNUM & MASON,

Piccadilly, London, W.

## FORTNUM & MASON

remind their numerous customers in the Army and Civil Service of their special Chop Boxes and Stores. These have doubtless been seen at all the large Centres overseas on their journeys into the interior.

## FORTNUM & MASON'S GROCERIES and PROVISIONS are world famous.

## FORTNUM & MASON'S PRICES

are in line with those of all houses of repute.

## FORTNUM & MASON'S WINE DEPARTMENT

is thoroughly up-to-date.

	12 years old.	10 years old.	9 years old.	6 years old.
<b>Whisky in bond</b>	<b>32/-</b>	<b>29/-</b>	<b>26/-</b>	<b>20/.</b>
	Per 1 dozen case.			

## FORTNUM & MASON'S EQUIPMENT DEPARTMENT,

Showing construction of bottle.

started in 1908, has everything of the most modern—Strong, Reliable, and Cheap. They invite especial attention to their patent "FORTMASON" Water-bottle, the invention of a Soudan Government Official to whom all the exigencies of the Saffarieh are well known. The feature of the bottle is the shoulder, which unscrews to admit a hand for the purpose of thoroughly cleaning the inside.

## EDITORIAL NOTES.

THE paper which has been presented to Parliament on the subject of the agenda of the forthcoming Imperial Conference indicates that a very full and varied programme has been arranged. In a despatch to the Dominions dated the 20th of January, Mr. Harcourt enumerated the subjects proposed for discussion by the various parties to the Conference. Some of these were eliminated as being more suitable for discussion at subsidiary conferences, but the following list of topics reserved for the full Conference should suffice to satisfy the most healthy deliberative appetite:—

- Merchant Shipping and Navigation Laws ;
- Cheaper cable rates ;
- All Red Route ;
- Imperial Court of Appeal ;
- State-owned Atlantic Cable and Telegraph line across Canada ;
- Publicity of Proceedings ;
- Imperial Representation ;
- The reconstruction of the Colonial Office ;
- Interchange of Civil Servants ;
- State-owned British Wireless Telegraph Stations ;
- Double Taxation, and Stamp Duties on Colonial Bonds ;
- Commercial co-operation for the encouragement of British Manufactures and Shipping ;
- The Declaration of London ;
- Emigration and the position of Labour Exchanges ;

Currency and Coinage ;

Co-operation between the naval and military forces of the Empire and the status of Dominion navies ;

The position of British Indians in the Dominions.

At the date of this despatch neither Canada nor South Africa had formulated any proposals for discussion, and the Canadian Government subsequently intimated that they did not desire to suggest any particular topics. South Africa, however, submitted the text of six resolutions, some of which may be regarded as falling within the scope of the programme previously arranged. The fourth of these resolutions read as follows :—

“ That the desirability be considered of replacing the system of Trade preferences at present granted by the overseas Dominions to Great Britain by a system of contributions in money or services to Imperial naval and local defence.”

The Union Government shortly afterwards decided to withdraw this resolution, but stated that the Prime Minister hoped to have the opportunity of discussing with His Majesty's Government the question raised by it.

---

Every endeavour has been made on this occasion to enable the statesmen who will participate in the Conference to prepare themselves beforehand by a study of the questions for discussion, but with the limited time available and a programme of such immense scope, the task is necessarily one of great difficulty. It is further complicated by the obligation, which our visitors from overseas can hardly escape, to attend during their brief visit many public functions and social gatherings. It may be anticipated that the Conference will seek to improve the arrangements already in force for carrying on its work continuously and systematically during the intervals between the quadrennial meetings, and this matter will naturally come up for discussion in connection with the proposals for the reorganization of the Colonial Office, to which Mr. Harcourt proposes to assign an early place in the programme. Sir Francis Hopwood is to resume his old position of Permanent Under-Secretary of State for the period of the Conference. In 1907 it was Australia which pressed most strongly for a reorganization of the Colonial Office, with the support of Cape Colony. On this occasion two distinct proposals emanate from New Zealand and South Africa. The former desires the complete separation of the Crown Colony and Dominions Divisions, each to be placed under a distinct Permanent Under-Secretary. The latter proposes to place the Dominions Division, together with the Secretariat, directly under the Prime Minister. The views of the home Government have not been stated, and will presumably not be definitely formulated until the feeling of the Dominions has been clearly brought out by discussion.

In Imperial affairs, the principal event of the past few months has been the conclusion of the agreement for reciprocal tariff concessions between Canada and the United States of America. The negotiations at Washington in the first instance attracted little attention. It was generally realized that the day of Canadian "pilgrimages" was over, and it was anticipated that any agreement would be limited in its scope and of only secondary importance. The conclusion of an arrangement introducing free trade in a large number of products and substantially reducing duties on many others took the world by surprise. It has given rise already to "full dress" debates in the Canadian Parliament, the Imperial Parliament, and the American Congress. Its probable effects on the agriculture, commerce and industry of Canada, on the future of such lines of communication as the Canadian Pacific Railway, the Grand Trunk Pacific Railway, the Hudson's Bay Railway, and the projected Georgian Bay Canal have been extensively canvassed. Its bearings on the general question of Imperial Preference have given rise to heated controversy. There is a considerable division of authority upon most, if not all, of these questions. But one fact stands out clearly. The consumer, whether in Canada or the United States, so far as it is possible to regard him as something more than an economic abstraction, and to isolate his interests from those of the producer, the transporter and the financier, is likely to benefit largely. The origin of the agreement is to be sought in economic and not in political causes. Ottawa has not had time or opportunity to forget the monster demonstration of the Western grain-growers in favour of a reduction of duties. Washington has been perturbed by the growing volume of the demand for a reduction in the high cost of living and for a genuine "revision downwards" of the tariff, delay in hearkening to which has already cost the Republican party dear.

It is incumbent on us to avoid in these pages a discussion of the possible political implications of the agreement. But we may be permitted to express the opinion that an agreement which is good for Canada—and on that question Canada must be the judge—cannot in the long run be bad for the United Kingdom or the Empire. The Government has strenuously denied the suggestion that the policy of the preferential tariff has been abandoned and has treated with dignified contempt the charge that American reciprocity is a prelude to American annexation. There has been some tendency in this country to overlook the fact that one result of the agreement will be to admit into the Canadian market either free, or at a reduced rate of duty, many articles from the United Kingdom and from other British dominions. In no single instance will American manufacturers enjoy in Canada a preference over their British competitors. Canada, in fact, in making provision for her own economic interests, has continued to show a steady regard for those of the United Kingdom.

There appears to be every probability that the agreement will be carried into effect. In Canada it has aroused, as was inevitable, a good deal of hostility. The Opposition as a whole is committed against it, and some Liberal supporters of the Government have disclaimed the policy of their party. But Parliament has given its approval, and there seems to be no doubt that the general feeling of the country is behind it. In the United States the House of Representatives has endorsed the agreement. The Senate, which has proved a fatal obstacle to so many international arrangements, has failed to approve it during its ordinary session. But it appears to be agreed that had it been possible to carry it to a vote, the decision must have been favourable, and in this instance the Senate had plausible grounds for maintaining that the time available for discussion was inadequate. Moreover, President Taft from the first made clear his intention to resort, if necessary, to an extra session—an expedient no more popular among legislators in the United States than in the United Kingdom—to secure the passage of the agreement. In the new Senate the Democrats will be in a majority, and the chief danger to the prospects of the agreement would seem to lie in the possibility of its being put on one side to make room for a more general reduction of the tariff.

---

It is inevitable that Canada and the United States should develop closer personal relations as time goes on. It is calculated that in ten years from now the greater part of the population of the Dominion will be west of Lake Superior, and there the American element and influence will be very strong. There are already strong points of resemblance in business matters between the Dominion and the United States, as contrasted with the United Kingdom. Their commercial laws and banking systems are similar; currency and mechanical standards are the same. No surprise need be felt at the movement for closer trade relations, and, with an annual immigration of some 200,000 Americans, it is fairly sure to grow. It does not, however, by any means follow that Canada will ever cease to preserve her distinctive character politically. Some observers foresee a time when the tariff wall between the two countries will altogether disappear, but in practice the dependence in both cases on taxation of goods for raising revenue will operate strongly against so complete a result. But whatever the outcome commercially, the Americans who settle in Canada are quickly imbued with the national spirit of the Dominion. They become proud of the resources and prospects of their new country; they respect the orderliness of the population and the firm administration of the law. Whatever may be said of regrettable exceptions, such as occur in Canada as elsewhere in a world of imperfections, the general standard of social and political life is a high one, and few persons will settle there without sharing

eventually in the public spirit and loyalty which characterise its people. It is true that the new-comers from the United States know and care little about the British Empire, but loyalty to Canada herself is the first necessary step. In the meantime the United States are likely to undergo a considerable personal change, owing to the influx from southern Europe, which is calculated to increase the divergence of national character.

---

Whatever may be said of other trade, the solid fact remains that Great Britain will be, as it is now, the great market for Canada's chief industry. Within three years, it is believed, the United States will not export, but will have even to import, wheat. When the Panama canal is opened, the grain of western Canada will reach Great Britain by that route. Instead of moving east in Canada it will go west. Even now Alberta sends to Liverpool via Cape Horn. The ships that come out with grain will not go back empty. A full cargo one way, as all shippers know, is a vast help to shipments the other way. It is to be hoped that the British manufacturer will utilize the advantage, and in view of the use he has made of the Suez canal it is more than likely that he will.

---

The discussions of the Canadian reciprocity agreement recall the parts played by two protagonists of political debate, the Marquis of Lansdowne and Mr. J. Chamberlain, in connection with the Dominion's relations with the United States. Commercial disputes between the two countries loomed large through the second half of the last century. The United States abrogated the reciprocity Treaty of 1854 in 1866, and though the fishery provisions were renewed by the Treaty of Washington in 1871, this Treaty was likewise abrogated, it is believed as an expression of dissatisfaction with the award under which the United States were required to pay 5,500,000 dollars for the privilege of fishing under the Treaty. In both countries there were, however, parties in favour of reciprocal tariff concessions, and, in 1884, it fell to the Marquis of Lansdowne to explain to the Foreign Office that "it is indeed a matter of notoriety that the Dominion has consistently expressed its readiness to become a party to an arrangement which might have the effect of affording increased facilities for international commerce between itself and the United States. It has given the best proof of its sincerity by taking under its existing Customs Laws powers, of which your Lordship is aware, to admit upon favourable terms by Proclamation of the Governor-General those products of the United States which were included in the Treaty of 1854, whenever a similar course in regard to the natural products of the Dominion may be adopted by the Government of Washington. It regretted at the time the termination of the Treaty of 1854,

which it believed to be advantageous to the interests of both countries, and it would be fully prepared, on receiving from the Government of the United States an intimation that negotiations would be likely to produce useful results, to enter into such negotiations in an amicable spirit."

---

The immediate result of the abrogation was to throw back the fishery question to a Convention of 1818, the construction of which led to a long and technical controversy. Eventually, in 1887, Mr. Chamberlain was appointed, with Sir L. West and Sir C. Tupper, to negotiate a settlement, and this difficult task was successfully carried out. So ended a long-standing course of irritation. It left, however, some feeling behind it, and other disputes which arose contributed to delay the friendly consideration of reciprocal trade.

---

Canada enjoyed another prosperous year during 1910, the process of recovery from the depression of 1907 and 1908 in consequence of the American financial crisis being continued and increased. There is no better index in this matter than the immigration returns, and these show that all previous records were surpassed, the total of arrivals considerably exceeding 300,000. Even these figures are expected to be exceeded in 1911. The agricultural returns were not quite so good as those of the previous year, but manufacturing concerns and transportation companies enjoyed increased prosperity. Fresh railway construction was continued on an immense scale, no less than 6,000 miles of track being in various stages of completion during the year. Employment in nearly all branches was active and wages tended to increase. On the other hand, the rise of prices, which appear to have extended to all countries, made itself felt in Canada, and the cost of living rose in consequence.

---

At this period there is the annual exodus of farmers, or would-be farmers to the West, and presently Canada will be enriched with a great number of sturdy settlers. The attraction is one which Europe cannot give; it is free land, and in most of the favourite places it is 160 acres. This quantity is arrived at as being one quarter of a square mile, which is usually taken as a section. In parts of the United States, where the land is not inviting, you can get a whole or a half section; on the other hand the Canadian Pacific Railway allows 40 acres, or one-sixteenth of a section, of irrigated land. The new Canadian Townships are formed in pieces of 36 sections or square miles, and when fully settled are reckoned to hold a population of 720 ( $36 \times 4$  homesteads  $\times 5$  persons). In Manitoba, Saskatchewan and Alberta about 18,000,000 acres have been disposed of in such free grants, leaving a trifle of some 86,000,000 for future applicants. Twice this amount is available

in the dry zone of South Africa, giving room for a population of one million. As these spaces fill up the necessity will increase for scientific farming and intensive culture.

---

It is, however, reassuring to the historically old parts of the earth, which are frequently decried as more or less played out in comparison with virgin territories, to find that an official United States report has declared that the older agricultural soils of Europe, as a whole, are not deteriorating, and that there is no marked difference between the composition of the old European soils and that of the new American soils in respect of potash, phosphoric acid, lime and magnesia. Not very long ago economists dwelt upon a supposed law of the diminishing productivity of land, and alarming inferences were drawn, but nowadays we hear little of all this. Individual farms deteriorate, and soils wear out, as has always been the case, but on the average an acre produces more than it used to do. This is, of course, largely due to better methods of cultivation and to the greater use of fertilisers. But even without such treatment there is a power of recovery in soils. It is mostly a question of nitrogen. The nitrates may be exhausted by excessive cultivation. But we know now that they are replaced, not by chemical action, but by bacteria, and in course of time this activity restores the land to a fairly high level of productivity. The great necessity is to give this process a fair chance by preventing erosion by water, and care should be taken that the drainage is not excessive.

---

Great Britain is now lending money to Canada to the amount of about £40,000,000 a year. The British public is certainly showing much greater confidence in the Colonies than was the case towards the end of the last century. Last year the visible capital raised here for Australasia was about £10,000,000, and the credit of the Territory has recently improved with the increasing production. The comparatively recent investments in South Africa amount to about £350,000,000, nearly equal to the whole amount which has been supplied to Canada and Australia. These three possessions and India have in fact received much the same sums. India has absorbed some £365,000,000, obtained at a very low interest, and this has undoubtedly been due to the autocratic control which has been maintained, but it must be admitted that the cost of developing India has taken up a vast amount of capital much of which would otherwise have gone to the building up of our Colonies.

---

Since the establishment of the Australian Commonwealth there have been repeated controversies as to the respective limitations of the powers of the Commonwealth and the component States, and in our last issue we drew attention to the proposals which are to be submitted to the Australian electorate for the amendment of the Constitution in this connection. The Commonwealth

Government has now taken a further step of no little interest with a view to lightening its difficulties. We have from time to time taken occasion to refer to the cases in which the Courts have held that the legislation of the Commonwealth was *ultra vires*, and it is unnecessary to enumerate these cases again here. It will be sufficient to remind our readers of the crucial decision which sufficed to frustrate the policy of the "New Protection." Under the Judiciary Act recently passed by the Commonwealth Parliament, the Government is enabled to submit to the Court for decision the general question of the validity of a particular piece of legislation. By this means it will be enabled to avoid the inconveniences resulting from a decision that legislation which has actually become and remained operative is invalid. In this country the absence of a "written constitution" has to a large extent saved us from these inconveniences, but from time to time a decision of the Courts suffices to upset the generally accepted view as to the actual law. The famous decision of the House of Lords in the Taff Vale case, and the more recent but not less famous decision in the case of *Osborne versus The Amalgamated Society of Railway Servants* are striking examples, both falling within the comparatively narrow domain of Trade Union law. It is also often possible to determine the validity of a statute—or perhaps it would be more correct to say to determine its effect—by means of a test action in which the particular issue to be decided is only of minor importance. But the Courts are not accustomed to determine abstract legal questions except when they arise from the concrete facts of a particular issue between parties. Similarly it will be remembered that one of the most important decisions ever given with regard to the constitution of the United States was in form only a decision as to the duty payable upon a cargo of hay. The expedient now adopted by the Commonwealth is novel but not unprecedented. Mr. Hughes was able to show that even in the United Kingdom the judges have on occasions been invited to express their opinion upon questions stated in an abstract form, and have not shirked the duty. But it undoubtedly constitutes an onerous addition to the functions of a court of justice, and as so doing came under adverse criticism from Mr. Deakin. We notice that a writ calling in question the validity of the new Federal Land Tax has been issued by a plaintiff bearing the ominous name of Osborne, but these proceedings are taken under the old law and may be compared to the suit initiated here to determine the validity of "Form IV." Should the new legislation prove successful,—for it must be regarded as more or less experimental—the decisions of the Federal Supreme Court should in time constitute a valuable storehouse of constitutional law. But it would clearly be easy to overburden the Court with its new duty, and it will be observed that it is open to the Government only, and not to the private citizen, to set the newly devised machinery in motion.

The New Zealand Licensing Amendment Act of 1910 makes important alterations in the law relating to local option. Hitherto, when polls have been taken, three issues have been submitted to the electors, namely, the continuance, reduction or abolition of licences. In future a vote will be taken only on the two issues of continuance of licences or "no licences." But the most noteworthy change in the law is that providing for a poll on the question whether or not licences for the sale of liquor are to be issued in the whole of New Zealand. The question of national, as opposed to local, prohibition is thus raised. Electors will be required to vote either for or against national prohibition, and in the event of three-fifths of the voters expressing themselves in favour of it, national prohibition will come into force on the expiration of a period of four years from the date of the election. If national prohibition is carried in this manner, a proposal for the restoration of licences is to be submitted to the electors at the first general election which is held after the expiration of three years from the time when national prohibition came into force. This proposal also will require, if it is to be carried, the support of three-fifths of the voters, but should such support be forthcoming it will take effect after an interval of three months.

---

The effect of the Australian legislation against shipping rebates possesses no little interest for other places which are agitating against the system. The enactment is perhaps not quite clear, but the inter-state steamship companies have bowed to the evident intention and have notified that the bonuses which they have paid to customers who give them the whole of their business will be discontinued. It is of course clear enough that this result can be brought about by legislation, but in this case the companies have retaliated by increasing the net freight charges. The shipper therefore loses his 10 per cent. and gets no advantage. In some quarters it has been urged that this result is a proof of the uselessness of such legislative attempts. But at any rate the law clears the road for competition. Whether competition will spring up in such circumstances is a matter which depends on the economic position. The law cannot create it; commercial demand may or may not. In Australia prices have gone up materially and the awards of the Arbitration Court tend further to put up rates. On the whole it seems likely that, irrespectively of the law, rates would have been raised under the operation of these causes. At such a time it can hardly be expected that the companies will compete against one another in the only form left to them, viz., by cutting rates. But from the public point of view it is something gained if competition is made possible when circumstances encourage it.

The South African bill provides that the Postmaster-General of the Union shall not enter into any contract with a shipping company

which offers any rebate in consideration of exclusive dealing with the company. Here again the practical question will be whether any effective competition can be established against the Union-Castle Steamship Company.

A "Committee of Colonial Intelligence for Educated Women" has been founded under the Presidency of H.R.H. Princess Christian of Schleswig-Holstein. The Hon. Mrs. Norman Grosvenor is Chairman of the Committee, which includes representatives of the British Women's Emigration Association, the South African Colonisation Society, and the Central Bureau for Employment of Women, and Mrs. John Buchan, 13, Bryanston Street, W., is Honorary Organizing Secretary. The objects of the Committee are stated to be:—

"1. The maintenance of an Intelligence Office which shall estimate the demand for women's work in the Colonies, and bring it into relation with the supply in this country.

"2. The establishment in the Colonies of expert agents who shall investigate local openings and report on them.

"3. The establishment in each Colony of settlements for women, where they can be trained for Colonial conditions."

The scope of the Committee's work is indicated in the following extract from the prospectus:—

"It must be clearly understood that the actual work of Emigration will not be undertaken by this Society. This work is already admirably done by the British Women's Emigration Association and the South African Colonisation Society. We hope to assist both these organisations and the Central Bureau for the Employment of Women in the difficult and intricate task of finding suitable openings for educated women overseas—a task which, owing to the enormous amount of work already on their hands, they have not found it possible to develop fully. It is proposed, therefore, to send out from this Committee to each Colony an educated practical woman who will investigate conditions of employment and new openings for women, and who will endeavour to establish a network of reliable agents throughout the Colonies. It is also hoped later on to found settlements in the Colonies where training, suitable to the needs of each Colony, can be given, and which will form centres to which the girls can return in the intervals of employment. It will at once be seen that both these proposals involve considerable expense, and contributions towards this much-needed work are earnestly requested."

The new organization, if it succeeds in its aims, will be accomplishing a very useful piece of work, and we are glad to note that care has been taken to prevent wasteful competition or overlapping with the work of existing agencies.

The Governor of the East Africa Protectorate states in his last annual report that "there would appear to be very little doubt

indeed that the Colony is about to witness considerable expansion in its European farming population. The progress which has been made in seven years in spite of many difficulties is very striking. Very few of even the oldest of our Colonies can provide the amenities of this, our youngest. There is hardly a farmer unprovided with communication by road—not always of a high-class character, but fully equal to that existing in any new country; one settlement only is fifty miles from the railway—the Uasin Gishu Plateau. The lands are mainly held in leasehold. This is held by some to be a deterrent to the country's progress—a contention which is, to my mind, erroneous. It is conclusively proved that the countryside will be agricultural as well as pastoral. Many of the farms, the bulk of which are from 3,000 to 5,000 acres in extent and have been granted on pastoral leases, will undoubtedly become agricultural. The rent charged is from a halfpenny per acre to threepence for the best agricultural lands.

It is a fact that in other countries, and notably Canada, freehold agricultural land is being granted. It is to be remarked, however, that it is limited to 160 acres, and that in most cases the best lands are in the hands of railway or other companies, and the settler seeking a free grant has to go far afield for it. If he seeks to come close to the railways, he finds virgin land standing at from £1 to £2 per acre. Moreover Canada, Australia and New Zealand are purely European countries."

The leasehold system, as we have pointed out in a previous number, will preserve East Africa in the future from the land difficulties which have befallen Australia, and it is not likely that farmers will be deterred by it.

In addition to the ordinary grant of East African land to settlers, there are the special cases of concessions on a large scale for the purposes of exploiting some natural product. The usual term for leases in such cases is 21 years. A shorter period may lead to an improvident and wasteful use of the land, as the lessees would have no interest in maintaining its value; on the other hand, as little is known of the market value of the grant and future prices might be much higher, it is always possible that a very long lease might prove to have been let on too easy terms. Only uninhabited land is so dealt with and therefore there can be no question of interference with native rights; natives have, therefore, to be recruited for the necessary labour, and it will be necessary for the Government to exercise proper supervision. It is usual to require that a substantial amount shall be spent during the first two years on the development of the estate.

It is satisfactory to find from their last report that the British North Borneo Company are doing well. The British Empire has been largely built up by the labour of trading companies, which have taken the risks and have been allowed by a somewhat indifferent

government to manage things after their own fashion. The idea that colonial territory may be regarded as an asset on which Government funds may be laid out as an investment is quite a recent one. It certainly had no footing in 1882 when the North Borneo Company got its charter. The Liberals were then in office and were much more disposed to let private adventurers take the field than to do it themselves. The debate in the House of Commons reads curiously now. Mr. Balfour took Mr. Gladstone to task for his jingo spirit. But this was when the fourth party was in existence. The next year under Lord Salisbury a Protectorate was established. It is clearly an important possession, if only in virtue of its position. It would not be pleasant if this island with its splendid harbours and useful coal mines, in the centre of the Malayan Archipelago, had been in the possession of another Power. The Company resembles a government even in its commercial capacity. It mostly follows the policy of granting concessions to subsidiary companies. Of these there were twenty-five in 1910. Some desire has been felt that the administration of the territory should be taken over by the Government, but the difficulties which have led to this elsewhere—foreign complications and the existence of a large native population—are not encountered here.

The doubts and controversies which have attended the progress of the British South Africa Company have formed a marked contrast with the absence of history which has characterised the North Borneo Company. The courage with which the original settlement, then remote and forlorn, was entered upon will always be a source of legitimate pride. The difficulties were enormous, and it is most gratifying on every account that the Company has at last turned the corner. This is pre-eminently, from top to bottom, a British enterprise. Trade has, in this case, followed the flag. For the present, development waits chiefly on the pick, but a great agricultural activity is in progress, and cereals, tobacco, cotton and other valuable products are coming on apace.

The formation of a British West African Association, similar in character to those which represent the West Indies, Ceylon and the Straits Settlements, is a step which has certainly not been taken too soon. Commercial interests on the West Coast have increased remarkably in recent years, and have commanded special recognition from the Colonial Office. In all these matters the personality of the late Sir Alfred Jones strongly asserted itself, and as often happens when a strong man fills the stage, there was little opportunity for others, but now there is ample room and reason for an organized association which will represent all classes of producers and merchants. We trust, nevertheless, that some one will presently arise, who will don Sir Alfred Jones' mantle,

and unite with successful commercial enterprise the keen spirit of patriotism and good endeavour which was the joy of his life. It would not be difficult to pick out from the first list of the Association some one who could fill such a rôle.

The address of the Association, of which Earl Cowley is President, is 1 and 2 Oxford Court, Cannon Street, E.C.

Sir Sydney Olivier's report on Jamaica for the year 1909-10, concludes with some interesting observations on the general condition of the Island, which we reproduce below:—

“The year was, on the whole, one of prosperity and progress for the Island, notwithstanding that some districts suffered from drought and others from the exceptional storm of November, 1909. The damage done by the November storm to bananas, cocoa, yams, and in a smaller degree to other less important crops, was considerable, and seriously affected the export of bananas and cocoa. The generally excellent weather of the succeeding period has, however, now completely re-established the condition of plantations and provision ground through the Island. At the date of which I write it would appear that the prospects of a good crop for the coming season are assured in all the districts of the Island in which the sugar-cane is cultivated for the production of sugar or rum. Unfortunately the disorganised state of the rum market may discount this advantage for those estates (considerably in the majority) which rely upon the production of Jamaica rum, and are not equipped with modern sugar-making machinery. I am glad to say that the tendency to equip sugar estates for this purpose has received encouragement by the success of recent ventures in the equipment of factories, and bids fair to progress further. The effects of the storm of November, 1909, which, whilst they were much exaggerated to the prejudice of the Island by alarmist telegrams at the time, were unquestionably violent and severe, but were met and combated with great cheerfulness, energy, and resolution by the classes affected by them, should serve as a reminder that the Island is much more largely dependent for its income and support upon one single very easy destructible crop, the banana, than is at all satisfactory. The encouraging experiences of sugar planters during the last ten years, and the improvement to the price of cocoanuts have accordingly been specially valuable in calling attention to the profits of those staples. The attraction of banana cultivation lies in the quick returns and high profits which it yields in successful years; but the periodical losses are considerable, and when the fields are blown down their yield is destroyed for a year. Tougher cultivations, such as cotton and possibly rubber, will probably not be greatly extended until the profits of planting bananas have been reduced by the

exhaustion of soils and the consequent increase of the cost of cultivation, and at the same time money has been saved for investment in more permanent and slower-yielding staples. The extension of the skilled cultivation of bananas (as distinguished from the same peasants' cultivation) still progresses: the United Fruit Company continues to lease or buy neglected properties and turn them into banana plantations; and I am glad to be able to report that similar operations with local capital, by syndicates and individuals, have also been witnessed during the year of report. These developments, when successful, are, however, I regret to say, not very frequently due to capital or personal ability introduced direct from Great Britain, although several opportunities have recently been offered to British investors to take shares in large undertakings for planting in this Island. The enquiry is frequently made whether Jamaica offers a good field for the investment of British capital in planting enterprises, or for a livelihood to young men with a moderate patrimony. There can be no question that planting in Jamaica has been yielding large profits during recent years; but these profits have been earned by the application of high ability in the handling and financing of large enterprises, either by corporations, such as the United Fruit Company, or by a few individuals in the Island, and of personal knowledge, ingenuity, and industry on the part of individual agriculturists in no inconsiderable numbers. The young men of the class with regard to whose prospects as immigrants enquiry is made have too frequently neither of these endowments, and both are indispensable to success. They may attain the latter, but they must serve a more than nominal apprenticeship before they can hope to make money in planting here. Nor, I regret to say, have the directors of certain British companies and syndicates that have taken in hand the planting or fruit dealing businesses in Jamaica shown that grasp of sound business methods and that appreciation of the conditions to be coped with which enables the United Fruit Company and others with American capital continually to extend their profitable interests in this Island, nor even, in some instances, a reasonable modicum of financial conscientiousness or prudence in their engagement. Such enterprises unjustly damage the good repute of the Island's resources which, to capable and straightforward enterprise, have yielded and continue to yield a substantial return."

---

The defeat and death of Senoussi, which are reported in the French papers, are hardly noticed here, though a few years ago he was a very disturbing influence on our West African Frontiers. He was one of the typical desert leaders, a Mohammedan, but of an independent sort, relying largely on religious fanaticism, and living

on the spoils of war. He came into notice in 1892, as the captain of several hundred riflemen. He soon entered into an alliance with Rabah, a chief of similar kind, and became a Sultan of importance in the North of Ubanghi. In 1899 he threw Rabah aside, and effected an alliance with the French. His new allies were so confiding as to furnish him every year with a certain number of quick-firing rifles. It is not altogether surprising that, with these resources, he proceeded to construct an active campaign of raiding. On one of these occasions, his son put some 20 natives in a cage and burnt them alive. Their offence was that they had run away from the slave traders. By 1909 he had from three to four thousand rifles, and was raiding far and wide. The French authorities found this "très gênant." They sent him an invitation to stop, and as he took no notice it was decided to fight him. At the engagement the French were about 210 in number, against 1,200, and evidently behaved with great gallantry and complete success. The result removes a terror which has sorely afflicted a wide district for many years. It is hardly likely that Senoussi will have a successor. His fate will probably have an effect in furthering the peacefulness of our own possessions.

---

An interesting discussion, which has been recorded in a sessional paper, has taken place in British Guiana on the principles of taxation applicable to such a place. There, as in most other Colonies, taxation consists chiefly of import duties levied for purely revenue purposes. These taxes are applied to the necessities of life, and are open to the obvious objections that they may press hard on those whose incomes are hardly sufficient to provide for such necessities. The Receiver-General argued that this objection loses much of its weight in a country where the conditions of life are so simple that the number of persons who are unable to provide themselves with the necessaries must be practically nil. There is, no doubt, much force in this contention, and the fact explains the universal practice in young countries of raising money in this way. The demand for setting up a difference between rich and poor does not arise at this early stage. Later on, when society is more complete, and the number of comparatively rich people greater, the principle of an income tax becomes more applicable. But, in practice, the system of direct taxation, when once it held the field, has a great advantage, and outlasts the original conditions. It is easy to increase the taxes if greater revenue is required; it is easy to urge objections to an income tax. When the amount of inherited property is small, the only substantial difference is between the successful and the unsuccessful workers. "Is it even fair," asks Mr. C. Grannum, "when two men start life without any very considerable disparity of opportunity, and one rises to an income of say, £1,000 a year, to tax him at the rate of, say, 1s. 6d. in the pound, while the other who

risers only to £200 a year, is taxed at the rate of, say, 1s. in the pound?" His own answer is that it is not, except in cases where incomes are so large that it is obvious that they have not been built up without the infliction of injustice on other members of the community, or where the condition of the State is such that money must be had even if it has to be collected by a system which does not embody justice to all alike. It is generally difficult to get the two men occupying the different positions indicated to agree about the justice of the matter, and as justice is not a simple thing, but a highly technical art, the question is not usually worked out so much on that ground as on the ability of various classes to pay. From this point of view the principle of progressive taxation has established itself. Up to the present the Crown Colonies have as a rule steered clear of income tax, and though the Straits Settlements have been brought face to face with the grisly phantom, it appears to have been exorcised for the present.

---

The decision of the Union-Castle Line to call once a month at Lobito marks the growing importance of this port, which has so much in its favour that it may become the most important point on the West African Coast. A proof of the enterprise now characterising the place is the installation of electric light obtained by damming the Catumbella River. The dam is of monolithic concrete and will hold up a head of 21 feet of water. The current is to be stepped up to 22,000 volts and transmitted to three sub-stations where the pressure will be reduced by step-down transformers to 500 volts for distribution. Three 225-k.v.a. turbine driven alternators are to be installed. The dam has been completed. The work may be taken as an example by other West African towns which possess streams which could be turned to account.

---

The progress of Katanga is of much interest to us, partly because its mineral wealth makes it important and partly because it is a place where the qualities of the competing commercial countries are put to a comparative test. We have received a book published by the Belgian Institute on Sociology which is highly complimentary to British enterprise and methods. There is certainly no trace in this description of detailed facts of the lethargy of which the British trader is being continually accused. The English language and currency predominate in the district. Official etiquette requires the officials to use French (the official language of Belgium) only, but the result is to relegate them to a state of "inaction" in commercial matters.

The making of the railway from Lobito is being hastened on. The distance to Elisabethville is 2,140 kilometres. The distance

from Beira by the present route is 2,615; but by the short out which is to be built with the aid of the Beit legacy this will be reduced to 1,575. The superiority therefore in point of distance will rest with the Rhodesian route, and for some time to come the commercial organization in Rhodesia will be able to command the situation. As regards the sea transit, Beira is much less favourably situated than Lobito. It is true that at present the freights from the former are lower than from the latter port, but this cannot last.

As Fiji is entering into the list of borrowing colonies, it is satisfactory to find that the revenue in 1910 exceeded that of the previous year by £27,158, and established a record. It is remarkable that the revenue at Levuka from import dues exceeded that of 1909 by almost 50 per cent. The principal factors in the improvement are the revision of the tariff, the increased output and enhanced price of copra, and a correspondingly increased buying power on the part of the natives. At the port of Lautoka the increase is to a large extent due to the expenditure of capital by the Colonial Sugar Refining Company, Limited. The earnings of the natives have been largely increased by a new industry, the collection and sale of a shell known locally as the "Sici," which is now largely exported to Japan and Germany. The improvement is the more welcome because not very long ago the finances of Fiji were in a state which in private affairs would have made for bankruptcy, and the necessity for retrenchment was so great that the salaries of the whole civil service were cut down. The appointment of Sir J. Thurston proved the turning point of affairs; the administration was carried on with a masterly hand and excellent results; and the deductions made from the civil servants' salaries were eventually repaid.

### Suez Canal.

It is estimated that by the beginning of 1914 the Canal will have been dredged throughout its length to a depth of 11 metres (about 36 feet), and widened to 45 metres (about 148 feet), measured at a depth of 10 metres (about 32 feet 10 inches). By that time, it is estimated that the depths in the channels at Port Said and Suez will be practically equal to those in the Canal. The maximum draught allowed for vessels passing through will be brought up to 30 feet, so that there may be under the keels about 3 feet under the most unfavourable circumstances, where shoaling may have occurred to the extent of 3 feet. It is almost certain that additional dredging and other works, principally with the object of further deepening the Canal, will be undertaken in the near future.

Eastern ports will of course make efforts to bring themselves into harmony with these improvements.

In our number of last October some remarks were made about fighting ticks in Africa by dipping the hosts on clearing spaces. We are informed that in St. Helena the mischief was dealt with by importing Indian Mynah birds (*Acridotherus tristis*). These birds thrive in the island and consume the ticks as they appear on the cattle. They might have been designed by nature for the purpose, as they attend on the cattle all day long, and no inconvenience has been caused by ticks for the last twelve years. They multiply very quickly, and would do so in Africa. They also clear vegetable crops of the caterpillar, which used to devastate whole fields before the birds were imported. The only objection is that they pillage fruit, especially peaches. We hope that they may be tried in Africa.

---

SURSUM CORDA.

When, in this life of little ease,  
 Our vision takes a wider range,  
 Where, compassed round by chance and change,  
 Our brothers toil beyond the seas ;  
 Then we behold, in scattered bands,  
 From where the bright Aurora belt  
 Shines in cold fire, to bush and veldt  
 And areas of burning sands  
 A race who, with a single eye  
 To duty, serve the Empire's need—  
 Spare handful of a precious seed  
 Sown amongst tares to fructify.  
 And whilst we mix with party strife,  
 Absorbed in insular concerns,  
 The exile spreads the flag, and learns  
 The wisdom of the broader life.  
 Unmarked, save when the Motherland  
 Assembles all her sons to swell  
 The pageant, or to bid farewell  
 When Death has severed man's command.

. . . . .

Far comrades on the Indian plains  
 Or on the dank Nigeria coast  
 Lift up your hearts ! The work at most  
 Is finite, but the fruit remains.  
 Lift up your hearts ! We may forget  
 The pioneers who won to fame ;  
 But there is glory in the name  
 Of undivided Empire yet.

## THE ADMINISTRATION OF WEST AFRICA.

- “The Niger and the West Soudan, or the West African’s Note Book,”  
by CAPT. A. J. N. TREMEARNE. (*Hodder & Stoughton, and  
A. H. Wheeler & Co.*) 6s. net.
- “Anthropological Report on the Edo-speaking People of Nigeria,”  
by N. W. THOMAS, F.R.A.I. (*Harrison & Sons.*)

THERE is no doubt that West Africa, though described as “undesirable, insalubrious and entirely damned,” exercises a peculiar fascination. The climate is more or less unhealthy, the scenery mostly dull and depressing, the life often rough and uncomfortable. Yet there are never wanting men who are willing to go there, and a large proportion of them feel the indescribable attraction of the place. The most obvious explanation is the opportunities which it gives. The agent or clerk finds himself in a new position; instead of being a mere machine he becomes an authority, and if he can keep himself going he is sure to rise. The young official usually touches a higher level of work and responsibility than is possible in any other part of the world. The frequent vacations at home help greatly to preserve the intellectual freshness. The West coaster shows an interest in all things West African, and is the backbone of more than one London club where sociability is a pronounced characteristic. The same man in the West Indies would certainly find a more comfortable home for himself and his family, but he would probably confine his attentions to his immediate surroundings, and would know little more of the adjacent colonies, if it is permissible to describe them as such, than if he had stayed at home. Perhaps at bottom the main reason why a white man comes to like the West Coast is that there is an enormous native population which, for practical purposes, is greatly inferior, and recognises the inferiority, to his own race. The life is dangerous and more or less primitive, but it ministers to personal

pride and the love of change and adventure. There is a freedom from conventionalities which has a subtle attraction, and the natives have on the whole a simplicity of character which makes them easy to get on with.

It would hardly be possible to reside in any part of West Africa without taking an interest in the racial history and characteristics of the people which inhabit it, and the attention which is now given there to anthropological studies is considerable. This is extremely important from the administrative point of view. The invariable result of such investigations is to show much meaning and value in ideas and customs which would otherwise be passed over as of no practical importance, and to suggest modes of building on the foundation of the existing system, rather than undertaking the unnecessary and perilous work of uprooting ancient methods. The sense of duty and of respect for authority has had in all countries to be evolved from the practice of centuries. But it is at best a delicate product, and if the established authority is suddenly destroyed it is impossible to replace it by any ready-made machine. It may be said that the leading mark of modern West African administration is the utilisation of native systems, and this accounts for the apparent ease with which effective control has been extended over the great spaces of Nigeria.

No doubt the old organization is already breaking down, or losing its original meaning. Speaking of the Edo district, Mr. Thomas observes that nowadays the only material advantage of becoming a chief seems to be the share in the fees paid by the new chiefs, which are squandered in riotous living. Each payment is made an excuse for a feast, and the only result is the impoverishment of the community. The pre-European tribal divisions, which to a certain extent regulated the work, are being dissolved by the increasing practice of the younger men to leave the villages to work on concessions. The general result is that the power of the heads of families and of the older men is hereby weakened. The process is clearly set out by the Governor of the East African Protectorate, where the circumstances are essentially the same.

“The elaborate structure of native custom and belief is apt to fall when we touch it, and yet we express surprise at the disorder of our own creation. We hold out inducements to natives to leave their homes, and yet we are astonished that these natives will not always return to their reserves. We cannot comprehend why, because they have tasted the sweets of town life, they will not carry on their former occupation in their own villages and hamlets under the rule of their chiefs and headmen, which rule we are endeavouring to maintain and strengthen. We forget that by bringing the native into contact with civilisation his mind may be rudely awakened; he discovers that he is naked;

he observes that others ridicule the superstitions, customs, and beliefs which he has hitherto held sacred; and he finds that his chief is, after all, not so important nor so rich as he imagined. In consequence he often prefers being a wage-earner to a capitalist, and following a free life to the discipline and restraint of his elders.

“The opening up of the country by European settlement, and the construction of the Uganda Railway and other public works, have tended greatly towards denationalisation. Civilisation is everywhere, outside the native reserves, marching apace; officials, missionaries, planters, farmers, merchants and traders, sportsmen and globe-trotters, one and all require labour, and one and all are adding their quota to breaking down the tribal systems, to denationalising the native, and to emancipating him from the rule of his chief. Although the native in European employment is at times worse housed and fed than in his own village, and the habit of daily work may be irksome, he feels that he is to a certain extent his own master, and if the employment is uncongenial he can legally terminate it. It is therefore in the interests of the employer to make him as comfortable as possible, and to try and persuade him to settle down and accept permanent employment. If he is well treated, is given ground for a garden, and earns sufficient to enable him to marry and live comfortably, why should he wish to return to his savage or semi-savage life in a native reserve? Apart, however, from his material comfort, we must, if we are to ameliorate his status and make him a more useful member of society, do all in our power for his moral welfare, as also towards making his improved condition a more permanent one.”

The native principles of law must yield largely to civilised ideas. Under the former, crime, except in extreme cases punishable by death and regarded as “God palaver,” was dealt with largely as a debt. In some districts even murder was settled by the purchase of a substitute by the offender. In a primitive community a utilitarian view is taken of such matters, and the first object is to repair the loss. When this has been done honour is satisfied. In practice it is quite possible that the system was as deterrent as the method of detention. The fines were substantial, having regard to the general poverty, or rather the absence of accumulated property. The immigration of labourers and the greater demand for production must, however, set up a more definite view of property and its right to protection. The education of the native will advance gradually in such matters in his own courts of law, and in the newly administered districts it is fully recognised that, so long as order is maintained, the best policy is to leave him to settle cases in accordance with his own sense of justice. In no country is it more necessary to bear in mind that it is impossible to expel nature with a pitchfork. Nor is there

any excuse for trying to do so, for owing to the climate West Africa must be developed by the work of the native, and their problems are not ours.

It is therefore fit and proper that in a book designed as a *vade mecum* of a practical character Capt. A. J. N. Tremearne has given a good deal of space to the anthropology of West Africa, a subject on which he is an authority. Much writing has been poured out on the topic, but a thoroughly scientific treatment is still to come, and the appointment of an expert in Mr. Thomas is a good step in this direction. Perhaps the study of origins is not particularly important to the administrator. Lucubrations as to whether the Stone Age held sway in West Africa as it did in Europe, or as to the respective infusions of Hamites or Semites are of little more than academical interest, considerable as that may be. But the actual beliefs and customs of the natives are a vital matter. In former times the chiefs maintained their authority by military powers. We have now substituted for the profits of raids more or less fixed stipends. This system, as elsewhere, in the long run wins over the chiefs. But in the first place it takes away from them the inducement which they had under the old régime to keep their people in order, and in the second place the shifting of authority and the introduction of new methods undermine the old relations. It must be recognised that sooner or later this is inevitable. Tribal or family institutions cannot hold their place when the necessity for them has been taken away. The West African native is in fact, as a rule, when in contact with a white race, quickly weaned from the traditions of his fathers. Whether he is individually a better man for the process is questionable. He passes into a state of liberty for which he has had no preparation, and which to him is morally equivalent to licence. Endowed as he frequently is with a sublime conceit, he easily absorbs the more objectionable traits of civilisation, and the results often induce a feeling of despair as to the possibility of dragging him up to a higher plane. Very pessimistic views have in fact been pronounced by experienced observers. Sir Harry Johnston says in "British Central Africa" that the negro "in his wild state exhibits a stunted mind and a dull content . . . which induces mental stagnation . . . and even retrogression towards the brute. . . . I can believe it possible that, had Africa been more isolated . . . and cut off from the immigration of the Arab and the European, the purely Negroid races left to themselves . . . might have actually reverted to a type no longer human."

The author of "Travels in West Africa" is equally emphatic. "I do not believe that the white race will ever drag the black up to their own particular summit in the mountain-range of

civilisation. . . . The African is not keen on mountaineering in the civilisation range. He prefers remaining down below and being comfortable. . . . And if he is dragged up into the higher regions of a self-abnegatory religion, six times in ten he falls back damaged, a morally maimed man, into his old, swampy, country-fashion valley." These are extreme conclusions which, we believe, are not by any means borne out by the facts. They are based on some disappointing results of attempts to develop the West African on European lines, but it must not be assumed that this is the only or the best method.

Opinion on the subject is largely influenced by comparisons drawn from the United States, Hayti, and Liberia. These cases may be held to establish the fact that the negro as a class is incapable of rising to a high position among civilized races, and is inclined to deteriorate after such contact if left to himself.

There is however a substantial difference between those cases and that of the West African at home. There he is not, as in America, living in the midst of a white race, in competition with them, and held apart and banned by them. Nor has he been uprooted from his origins and then left to evolve his own imitation of civilized administration, as in other places. The hope of the future is that the development of the West African races will proceed in their own countries on more natural lines. They have there the great advantage that they are not looked down upon and ostracised. Their country will never become a home to the European labourer, and there is no occasion for racial feeling. Every year, we believe, increases the feeling of confidence and respect on both sides. A great shock occurred when the outbreak in Sierra Leone in 1898-99 occurred, and the atrocious crimes which were then committed, in some cases by natives who were supposed to have been Christianised, made many people jump to the conclusion that the negro is irreclaimable. There was evidence at the time that the guilty tribes were exceptionally given over to superstition, that no effective control existed in what is now the Protectorate, and that the house-tax was introduced without preparing the native mind for it. Other causes of the outbreak have since been seen in their proper importance. There was at the time a demand for labour on the Congo, and all the young men who were available were promptly shipped off to that country. When they came back, accustomed to the system of wages, they were not inclined to work for the chiefs for nothing. This broke down the old control, and it was only in human nature for the chiefs to rebel. No sign of a recrudescence of violence has occurred since, but in the character of the administration the lesson has not been thrown away. Thus in the school for the sons of native chiefs at Bo, which was opened in 1906,

the boys are given ethical teaching but their religion and traditions are respected. "Under existing conditions pupils educated in Freetown invariably return home with a feeling of contempt for their native towns, and even for their nearest relatives. To prevent this both the native teachers and pupils will be expected to wear *country clothing*, and their lives outside of school hours will be spent in a small town, the government of which will be upon ordinary native lines. They live in their own village, in native houses, each of which contains five boys, one of whom is chosen 'head man.' Most of the households show great method in their division of labour, and the inmates are swift to resent and punish laziness and neglect, and careful in seeing that cleanliness is maintained. Boys are encouraged to write letters home, and constantly do so, and it is not uninteresting to observe in their frequent requests for pocket-money, country cloths, and other delicacies from home, a strong similarity to the habits of the schoolboys of their own years in England."

Throughout the West Coast the tribes have now settled down to a state of peace and order which has exceeded anticipation. They are, in fact, like most natives, ready to accept authority when once its force is proved. They view the position with philosophical calm. It is fate. The commercial instinct then develops at leisure. As soon as this process sets in generally, vast economic possibilities are opened up. The population is a great one; the products are rich and varied. Agriculture, which will be the mainstay, will be left to the native. The negro is at his best as a peasant proprietor as may be seen in the West Indies. The "concessions" which have been granted in many cases on a liberal scale to companies and syndicates and have come lately under the ban of much suspicion, are after all not really grants of the land. They are grants of certain rights over the land, mostly mineral, which the natives do not prize and could not properly work, but the customary rights of the natives are reserved. There is no question in such cases of ousting resident natives, and the creation of new markets in their neighbourhood is of course to their advantage. There is no real antagonism of interest between whites and blacks as there is in South Africa. Moreover, from an economic point of view, the West African is more promising than the Kaffir. He absorbs the requirements of civilization more appreciatively, and becomes a better buyer. This characteristic, of course, does not influence the British market much until he has got past the stage of native production. Thus it cannot be expected that Kano will deal extensively with Manchester as soon as the railway is at work, and even the cotton which is being grown under Lancashire auspices will in the ordinary course go mostly to native looms. But that a big exchange will

grow up in no long time is certain. The main difficulties have been overcome and the future promises to run smooth under an administrative policy which acknowledges the native ownership of land, respects tribal customs, maintains the native courts, regulates taxation in accordance with native ideas of justice, and sets itself to promote technical education and rational methods of dealing with the products of the soil. We borrow a further extract from Sir P. Girouard's East Africa report which puts the matter in trenchant language.

"The fundamental principle, and the only humane policy to be followed in dealing with peoples who have not reached a high stage of civilization, and are still dependent on a communal system of government, is to develop them on their own lines and in accordance with their own ideas and customs, purified in so far as necessary. Whilst retaining all the good in their government which makes for manliness, self-respect, and honest dealing, only that which is repugnant to higher ideals of morality and justice should be rejected. All authorities on African native government have deplored the great harm that has been done, not purposely but unwittingly, by administrative officers possessing little or no knowledge of the language, habits and customs, institutions, and traditions of the people they are called upon to administer. Impatient for so-called progress, they have at times trampled under foot the very institutions which should have been preserved if they had had any regard for the essential advancement of the people. Great and enduring patience is therefore expected from all administrative officers, for, exasperating though it may seem to see things go slowly, it is worse to upset ideals and customs so little understood. It is not from the present generation that we may look for much; the succeeding generations are in the hands of the administrative officers, and it is for them to mould the people as best they can with the educative means at their disposal. It must certainly be their endeavour to lift the natives to a higher plane of civilization, but this can only be achieved by gradual methods and by observing existing conditions. Every improvement must be by a natural process of evolution which will cause no extreme dislocation of present circumstances. We should support the authority of the chiefs, councils of elders, and headmen in native reserves, and the prestige and influence of the chiefs can be best upheld by allowing the peasantry to see that Government itself treats them as an integral part of the machinery of the Administration. Native tribes vary greatly; and whilst some have a natural genius for self-government others are more primitively constituted. Many of the tribes in East Africa have no chiefs of recognised authority, but where this is the case tribal or family authority is vested

in a chosen council of elders. By upholding the authority of the chiefs and elders it is not intended to imply that officers are to sit down and enforce blindly all orders issued by these men who, after all, are in a sense savages. The main object of administering the people through their chiefs is to prevent disintegration amongst the tribe; but active interest, supervision, and guidance on the part of the officers of the Administration are all necessary for the prevention of abuses. There are not lacking those who favour direct British rule; but if we allow the tribal authority to be ignored or broken it will mean that we, who numerically form a small minority in the country, shall be obliged to deal with a rabble, with thousands of persons in a savage or semi-savage state all acting on their own impulses and making themselves a danger to society generally. There could only be one end to such a policy, and that would be eventual conflict with the rabble."

## EARLY DAYS IN CEYLON.

So on he sailed from zone to zone,  
 Till he came to the Garden of Eden, Ceylon ;  
 And the devil chuckled with might and main,  
 As he thought how his mischief he there began,  
 When he first declared war 'gainst the race of man !  
 Now it chanced to be "upon a day  
 In the merry, merry month of May :"  
 He found it so hot he began to roar,  
 And, what's strange for the devil, he cursed and swore,

And he fled to his boat with hurried pace,  
 In haste to quit such a roasting place ;  
 And, going he shriek'd with doleful cry,  
 "It's high time for me back to hell to fly :  
 If I've any refractory spirits there,  
 I'll send them to Trinkomalee ;  
 'T will be pretty warm work for them to bear.  
 Since it's even too hot for me !"

*Old Colombo Journal.*

In the year 1782 there was published in Germany an account of the life and travels of John Christopher Wolf, Principal Secretary of State at Jaffanapatnam in Ceylon. The author appears to have run away from his home near Berlin and to have made his way in a sailing ship of a more or less piratical character from Amsterdam to Ceylon, where he landed in a destitute condition. But he faced the situation with national determination. He set to work to learn Dutch and Portuguese. He ingratiated himself with the powers that were and the story of the recognition of his merits may be of interest if only by way of contrast with the almost inhuman methods with which secretaries of state and governors are in these times wont to trifle with the claims of the deserving. "My diligence did not pass unobserved by the Governor. One morning he conversed with me in a very friendly and familiar way ; and at last concluded with saying, 'but may I absolutely depend upon your fidelity,

obedience, and discretion ?' I replied, 'I would pledge my very soul upon it.' 'But would I swear this by the Holy Trinity ?' I answered, 'with all my heart,' and took the oath accordingly ; after he had previously threatened me with the rack and gallows, in case I should prove untrue to him. After this, he gave me a key, and took me to a chest of books, fast locked up, in which all his private papers, containing the most full and accurate instructions, and exposing the real principles of government in that part of the world, were found disposed in the best order. 'By the perusal of these,' says he, 'you may acquire knowledge, and become master of your business : but in order that I may be able to judge of the progress you make, you shall write some remarks on the principal things you meet with worthy of observation.'—By these means I became, in a year's time, fit to be employed in state affairs, of which, an unexpected event obliged me to give a proof sooner than I thought to have done. On this occasion the Governor appeared extremely well pleased, saying, at the same time, 'I could never have expected so much of you. You are now come to that pitch, as to be capable of serving me essentially.' And to show how much he was pleased with me, he gave orders for a silver hilted sword, with an elegant embroidered sword-knot, the whole accompanied with a suit of blue velvet, to be made for me. My sword he put on himself ; at the same time clapping on my head a hat of great value, and saying, 'Now you are a gentleman.'"

The favour of the Governor extended so far that he offered the author his brother's daughter for wife. Herr Wolf, however, explains that "I politely excused myself ; on which account I was out of favour with the Governor, for more than half a year. This period of my disgrace might, perhaps, have lasted longer, if the Lady had not, in the meanwhile, got married to a Governor's son. It is true, I should, in all likelihood, have made my fortune early in life, by this match ; but I could not help having some apprehensions on account of two things, which I choose to pass by in silence." He shows in this matter a commendable, if somewhat disappointing reticence, and it is clear from his story that he owed much to a well-disciplined discretion, which must have been rather severely tried on some occasions. It would have been interesting to have had some account of the "full and accurate instructions," and probably in that case a useful comparison might have been made with that valuable code known as the Regulations for His Majesty's Colonial Service, which is no doubt regarded with the like veneration by British officials. The author, however, carefully guards himself from lifting the veil of secrecy. But he has the highest praise for the Dutch administration. "I openly before God, and with a safe conscience can say, to the honour of

the Dutch nation, that in this cabinet I learned, saw, and practised no other maxims of state than those, by which the Christian Religion, together with an impartial distribution of justice, may be kept up, without the molestation of any one, and at the same time the public peace be preserved. And with this protestation I close this cabinet, remembering my oath, from which I do not even now consider myself as free."

On the whole this encomium seems to have been deserved. The Dutch undoubtedly tried to administer justly, though occasionally their methods would hardly commend themselves to modern ideas. Thus no offender was doomed to death until he himself had confessed his crime. This appears to be on the side of humanity, till we read that if he would not confess, though found guilty, he was put to torture. However the law was carried out fairly, and Dutch evil-doers were treated with no favour. Liberty of conscience was fully allowed, and all religious disputes were discountenanced. They established numerous schools, and in this matter set an example which the English were slow to follow. It was a source of grief to them that their teachings had little effect on the religious beliefs of the Island, and in one matter they were greatly embarrassed. They could not quite reconcile Christianity with slavery, and it was unlawful to baptize a slave. On the other hand they did not see their way to doing without slaves. An ingenious device was for a master to have his slaves baptized by a Catholic Missionary, a step which was apparently considered good enough for religious purposes without involving the master. Apparently the progress of Christianity was seriously impeded by the bad example set by many of the newcomers. We do not find any striking evidence of depravity, and that the standard of conduct was put extremely high is testified to by the following edifying and no doubt veracious story:—

"Among the common people which come here from Europe, there are frequently found many that lead a sad dissolute life, as they know their conduct is not so closely inspected by the clergy here as it is with us in Germany. On two fellows of this kind, we once saw a remarkable instance of Divine vengeance inflicted: they were both sailors, that made swearing (as it were) their profession, and at that time were inventing new oaths to abuse each other with, and in which they endeavoured mutually to out-do one another. Now just as they were pleasing themselves with the idea of having invented a new and horrid oath, the master of the equipage ordered them to go off with a boat to a ship lying off the shore of Colombo, and bring away from thence a subaltern officer, whose presence was required at the fort. They did as they were ordered, and lo! they had scarce got to the distance of two gun-shots from the shore, when they both sank, in the sight of several people, in very calm and pleasant weather, and were never seen any more."

It will be remembered that there are similar illustrations of retributive fate in *Pickwick*.

The lot of the Dutchman on the Island appears to have been far from a happy one. The dangers and discomforts of the long voyage were of course always serious, and are narrated by the author with a detail in *Robinson Crusoe* style. On arrival the climate was found very trying.

"In such spots as the wind cannot arrive at, or thoroughly ventilate, by reason of their being situated in the neighbourhood of high mountains or thick forests, the air is very unfriendly to any new-comer from Europe. There are, however, many posts, which it is necessary to occupy with Europeans: some of these wretches I have often seen (not without compassion) in the most miserable condition, who, were it but possible, would willingly have been in their own country, begging at other men's doors; but a poor sinner is often made to repent in this country the crimes he has committed in his own." We trust that no such case occurs now. With all drawbacks, however, a great trade was done, and the author gives a great amount of information about the fauna and flora of the Island. Amongst it is a long account of the pearl fisheries, now so well known in parliamentary circles in this country. These were so well established even then that "some hundred thousands of people" assembled to buy the pearls, and the produce was valued at five to six hundred thousand dollars for a period of three years, for which it was farmed out. Large fortunes were made by the lucky ones.

"The poor European soldier, who with many others, to the amount of several companies, is sent hither by toilsome marches, to see that no malpractices are carried on, is an uninterested spectator of this private traffic; not but that he wishes (and that not a little) likewise to become a chapman, as he has heard from every body, that he might sell these commodities again to great advantage; but alas! his purse is quite empty, and so far is he from being able to buy pearls, that his finances will not even afford him a pipe of tobacco."

That Paradise was situated in Ceylon was firmly believed at one time by the settlers. In the first place there was the Adam's apple, beautiful in appearance but rank poison within. Then there was more specific evidence. "On a prodigiously high mountain, called Pico d'Adam," wrote Herr Wolf, "are found two tomb-stones, to the full as large again as the ordinary ones, with an inscription engraved on each, which hitherto no one has been able to read or write. Now there can be no doubt but that under these stones lie the bodies of Adam and Eve, who, as being the first of the race, are certainly entitled to this honourable distinction." The reasoning may not be convincing to the modern mind, but it was quite satisfactory at the time. After this it was an easy step to Adam's bridge, thrown over by our progenitor so that he might walk "with

his beloved consort from this Island, over to the Malabar coast." Perhaps it is owing to this particular sanctity that the elephants of Ceylon hold their heads higher than those that come from other parts, for "it is reported that when they chance to meet together these latter give them the pas and show evident signs of submission and respect."

The chronicles of early Ceylon history are largely devoted to the memories of kings, as in our own case, with their usual concomitants of intrigues, wars and sudden deaths, but they shed a glow of philosophical feeling over these incidents which is absent from our more humdrum productions. If a great man is murdered, the question is put: "What wise man, after being informed of this, would covet riches, life or prosperity?" A fall in life elicits the observation: "Thus worldly prosperity is like the glimmering of lightning! What reflecting person, then, would devote himself to the acquisition thereof?" These are certainly somewhat pessimistic sentiments, and it is not surprising to find honour paid to those who, to quote one way of putting it, "illustrating the destiny of the world, abstract the mind from the desire to protract existence." Perhaps this indifference explains the readiness with which the Cingalee acknowledged any ruler who could reach the throne, easily won by treachery and as easily lost. The royal fortress of Sigiri often changed masters, but never stood a siege. Passion was the rule of conduct in royal circles, and a large number of kings came to a violent end, but the general life of the Island owed much to the Buddhist system, essentially moral, contemplative, humane and peaceful, contrasting with the trammels of caste and the bloody sacrifices associated with Brahminism. No doubt it was possible to overdo things in the practical application of this system to public affairs. This may be seen from the sad end of King Sirisangabo, who, to quote Major Forbes' "Eleven years in Ceylon" (1841), "was a rigid devotee, and had taken the vows of the order 'Attasill'; the ordinances of which, together with the observance of many rules of devotion and acts of self-denial, totally prohibited the destruction of animal life. It may readily be conceived that the feebleness of a government administered by so bigoted an enthusiast soon led to anarchy. Crimes of the greatest enormity, committed with impunity, rapidly increased in all parts of the kingdom. When the malefactors were brought to the prison of the capital, as the King's vows precluded the possibility of their being executed, they were secretly released at night after condemnation, and the corpses furnished by the usual casualties of a populous city were exhibited at the place of execution, on gibbets and impaling poles, as the victims of the violated laws. By these means, says the Buddhist historian, a pious King successfully repressed crime, and yet gave the criminal time and opportunity to reform. The result, however,

as might have been expected, was precisely the reverse of that representation. The whole frame of society was disorganised ; and a famine, with its usual concomitant, a pestilence, combining with these public disorders, Goloo Abhaa, who then held the office of treasurer, easily wrested the sceptre from the weak hands which then swayed it. Sirisangabo offered no resistance. He privately left the city, taking with him nothing but his 'pirankada' (water-strainer), which is used by devotees to prevent the destruction of the lives of the animalculæ which they would otherwise imperceptibly swallow in drinking unstrained water, and met his fate while wandering as a hermit at this rock of Hattanagalla."

The Dutch policy was to treat the Emperor with the greatest respect, and on any audience they addressed him kneeling on one knee. Their concern was mainly the trade, and this they secured. The arrangement was really convenient to both parties. It is described by Herr Wolf in terms which suggest the underlying principle of the Modern Protectorate.

"The Emperor of Ceylon, in his present situation, may be considered as sovereign of one of the finest islands of the inhabited world. He resides almost in the middle of it, and sees the Dutch keeping watch round about him every where on the coast, that he is not attacked by an enemy unawares. It is true, he is by this means somewhat limited, and has not the liberty of trading with any other nation ; but this is of no import, he is Emperor notwithstanding, and his security must always be of greater value to him than any advantages by which his sovereignty might be endangered."

The year of the publication of this account marked the coming of the new rule, for in 1782 Fort Ostenburgh, at Trinkomalee, was taken possession of by the British.

## IN THE TIME OF KING THAKOMBAU.

THAKOMBAU was King of Fiji when that group was ceded to Great Britain. The proper native way of spelling the name is Cakobau, the letter *c* having the sound of *th* and *b* that of *mb*. Mark Twain says that foreigners always spell better than they pronounce. Perhaps inherently recognising this, the bluejackets on the station generally called His Majesty, Cockaboo. There is a story, probably untrue, that the Governor of Fiji, shortly after the hoisting of the flag, was expected off to dine on the man-of-war then on duty in the Islands, but His Excellency at the last moment became indisposed, and when the captain's boat came ashore for him, sent one of his staff to make excuses. That gentleman, for an Englishman, was swarthy in the extreme, so much so that he was considered by the simple bluejackets as a superior and educated sort of Fijian. The old Government House jetty steps were steep and greasy, and he slipped on them and barked his shins and expressed his feelings with language suitable to such an occasion. After the boat had returned to the ship and the crew were dismissed, the quartermaster ranged himself up alongside the coxswain and asked for news of the shore. "Oh!" replied the commander of the galley, "the bloomin' Guvnor's got an 'eadache and we've brought off Cockaboo's son instead; but my word, Bill, can't he speak English!"

Although this is an attempt to interest people in Fijian matters by writing in a light vein, there is no intention of really deriding King Thakombau, or those who worked so hard to help him establish a fixed and stable form of government, in what a local song used to call "the dear old cannibal days." That was in 1871, when goodness knows the times were bad and hard enough. To use the present colloquialism, the bottom was just falling out of cotton planting and most of the planters were at the verge of ruin. They were, with some Americans, mostly of

British extraction, who had tried their luck in Australia and New Zealand, and lured by the high price of cotton during the civil war in the United States, had come on to Fiji. The natives then were about 150,000. So, at least, it was supposed, but there was no effective way of taking the census, all the inland tribes of Viti Levu, the mainland of the group, being man eaters, always at war and therefore impossible of being counted. Any one brave enough to make the attempt would probably have been added by assimilation to the permanent population. However, the maritime tribes and those closely adjacent had for a long time been under the influence of the missionaries and were Christians. They were well in hand under the sway of their own hereditary chiefs and greatly outnumbered the cannibals of the interior. Most of the whites were young, rollicking and adventurous. They demanded the most democratic form of government, which was, of course, totally unsuited to the Fijians, who were used to an aristocratic and patriarchal system. As the settlers were mostly British they fell back on their own old time-honoured institutions, and business was started by a House of Commons elected by the white population, a House of Peers formed by the hereditary native chiefs and a Sovereign in the person of King Thakombau. Over all waved the national flag, which sported a red escutcheon charged with a white dove bearing in its beak a green olive branch, and the motto was "Rerevaka na Kalou, Doka na Tui," which being interpreted means, "Fear God and honour the King." His Majesty, it is reported, was heard to say that he did not like his flag, as it reminded him of a fowl being boiled in a pot, and the European opposition used to sarcastically allude to it as a dying duck in a thunderstorm. But the motto was distinctly good and we still retain it with the coat-of-arms granted to us as a Crown Colony.

Imitation is the sincerest flattery. We tried to adopt our dear old institutions. With them we had something very like an Irish question. At any rate we had a disaffected portion of the group over which presided a Viceroy. History has in many ways repeated itself in the Southern Ocean. Whilst great events were stirring in northern latitudes, similar ones, equally great in proportion to the relative state of affairs, were occurring in the Pacific. The traveller on the beaten track of the All Red Route between Australia, the Fijis, Hawaii and Vancouver, may see engraved on the rocks at the Pali, just outside of Honolulu, how there, in 1799, King Kamehameha drove his enemies over the precipice and consolidated his power in Oahu. That was the year of the battle of the Nile. Whilst we were fighting our Crimean and Indian battles in the early reign of Queen Victoria, vikings were still ranging the South Seas, and one of them, a Tongan adventurer by name Maafu, had begun to

establish himself in the Lau Archipelago, the eastern or windward islands of the Fijian group. Captain Cook, whilst at Tonga or the Friendly Isles in 1772, noted that the young bloods there acquired their military fame and did the grand tour among their Fijian neighbours, who were then considered, and very justly too, the most warlike and savage of the nations in those parts. How few know that charming little book "Mariner's Tonga," which treats of the author's captivity there in the early years of the last century! He bears out Cook's observations on the influence of Fiji on the character of the Tongans. In those days the latter were considered inferior in warlike prowess, but in our days by their superior intelligence and assimilation of European ideas the situation became changed.

Maafu was of such high rank in Tonga that there was scarcely room for him and King George Tubou, the reigning monarch. It was politely hinted to him that Fiji offered a fine scope for chiefs of daring and resource and he was supplied with war canoes, the new and greatly dreaded muskets, and such adventurers as cared to try their fortune with him. So he sailed from his native shores, never to return thither, save as a visitor. Hitherto the Tongans had but temporarily gone to Fiji as free lances, returning with booty and plunder. But under Maafu they affected a definite lodgment. By fighting and diplomacy, setting one small chieftain against another, he established his sway throughout the Lau Islands, the eastern or windward portion of the Fijian group. Probably he would have subdued the whole of it had he not have been resisted by the British consular officers, who consistently supported the legitimate rights of the native owners, and by the aid of our men-of-war checked his power. Seeman in his mission to Viti, *tempus* 1859-1860, gives a most picturesque account of how Commodore Seymour, in H.M.S. "Pelorus," compelled Wainigolo, Maafu's lieutenant, to evacuate the Macuata district. The description of the departure of the Tongan war canoes as they passed, with their crews cheering, under the stern of our flagship, is particularly fine. But only those who have seen a large fleet of native canoes with their huge triangular mat sails, with their war drums booming and painted crews yelling for all they are worth, can realise the picture.

Maafu in Lau proved an enlightened ruler, and with the aid of some English gentlemen endeavoured to introduce law and order. Before the proclamation of the sovereignty of Thakombau over the whole of Fiji, the islands under Maafu were banded together under the name of the Lau Confederation, the native name for which was the Tovata, which is still, in the Fijian, the designation for the United States of America. The idea was the union of the small islands known as Yatu i Lau, or Lau Archipelago. Many wise regulations

were there adopted, which subsequently upon the annexation by Great Britain, were extended to the whole of the Colony. Notable amongst them was the prohibition of the alienation of native lands and the substitution instead of tenure by lease, thus preserving the property for the original indigenous owners. When the late Sir John Thurston and Mr. George Austin Woods consolidated the power of Thakombau as King of the whole group, Maafu gave in his allegiance and received the title of Viceroy. But he was never loyal to the new administration. As in Tonga there was not room for him and Tubou, so in Fiji he could not brook the superior authority of Thakombau. He continued his intrigues among the chiefs and laid in great quantities of warlike stores, and was on the eve of commencing hostilities when the Union Jack was hoisted. Thakombau, aided by his European advisers, saw that that was the only way of preserving peace, and Maafu, seeing that events were too much for him, also gave in his adherence to the new government. He was made Roko or native Lieutenant-Governor of Lau, and having yielded to superior force that he could respect, remained a loyal servant until the day of his death.

As we had so many good old British institutions, a King, a Viceroy, and a House of Lords and Commons, we had to have all the rest of the paraphernalia. Thakombau, up to the time of his adoption of Christianity, was a most notorious cannibal and dreadful warrior. Once an enemy, a rival chief, was brought captive to him. It is said that he plucked out his enemy's tongue, eat it before his face, and then brained him with his ironwood war club. This dire instrument was sent to Sydney and was there festooned with silver doves and olive branches, and came back to be the mace of the House of Commons. When the sovereignty passed to Queen Victoria, the erstwhile weapon of the Vunivalu or War Lord of Fiji was sent to her in token of homage and fealty, and now probably is stored with other treasures of the Crown, where, let us hope, it rests in peace. But before that, like its prototype our own mace, the bauble was removed when His Majesty and his ministers subsequently usurped the power of Parliament. Of course there was a Speaker, and he lived up to his office by giving dinners and garden parties. As we had no road to speak of, we arrived thereat by means of boats, and we might well have been taken for a part of old London with its processions of barges, and Levuka in those days used to be very gay. Then there was the regular army, which, with its reserves, the painted club and spearmen of the feudal chiefs, was employed in fighting the cannibals of the interior, where it did remarkably good service. The headquarters was naturally at the capital, the streets of which were enlivened by the uniforms of the officers, which were modelled on a cross between those worn in France and America. The headgear were like kepis, and altogether there was a good deal

of gold lace. We were a young and an excitable community, and perhaps not quite so sober as we are nowadays, and like the heroes of Major Flushfire's song in Marryat's "Rattlin the Reefer," inclined to drink when we were thirsty and when we were not thirsty, and occasionally assisted in drinking matches. Parliament had not yet imposed customs dues, and Hollands gin was popular and cheap. It is white and innocent-looking, and in a glass water-bottle looks like what that vessel is supposed to contain. Such a one stood on the green baize-covered table, just below the mace, and, scandal has it, contained something stronger than water. Most stories are chestnuts, and probably this one dates back somewhere to about the time of Thebes; but it is said that after a stormy debate prolonged until close upon the dawn, an excited gentleman who hailed from somewhere in the north, insisted upon reciting "A Man's a Man for a' that," whereupon, after he had finished, another jumped up and said, "Mr. Speaker and gentlemen of the House: When Shakespeare wrote 'Write me down an ass,' do you think that he had in his mind the honourable member for Taviuni?" Then came into use another good old institution, the Serjeant-at-Arms, in a gallant effort to preserve the King's peace.

All went gaily for a while, but the inevitable crisis came, and His Majesty's ministers were outvoted and expected by the white inhabitants to resign. Many years ago there was an article in the old *Saturday Review* on a paragraph that had appeared in one of the dailies to the effect that there had been a ministerial crisis in Spain. It observed that when you play a game you must do it according to the rules, and that as Spain was indulging in constitutional government an occasional ministerial crisis had to occur, but that in matters of real import the Captain-General of Madrid had to have his say. With us the determined ministry, backed by His Majesty, the feudal chiefs and the army, refused to resign, and King Thakombau reigned on and did not meet with the fate of Charles the First.

Who can tell with what indignation the white settlers received this unconstitutional procedure? With the natives it was the proper chief-like behaviour under the circumstances. Each community took it according to its national characteristics. The Germans, of whom there were but few in those days, took it fighting. They had no warships in that part of the world then, and were a law unto themselves. Not so the unfortunate British; they were between the devil and the deep sea. England was playing the game of the dog in the manger. It would neither annex Fiji nor recognise the Thakombau government; yet, if its subjects resisted it, they were liable to deportation by the nearest man-of-war, and, as a matter of fact, some of them, for doing so, were arrested by the captain of H.M.S. "Dido." When the time for which supply had

been voted expired, the Germans refused to pay any more customs dues, seized their bonded goods, and fortified themselves in their principal warehouse. They were besieged by native troops, and bloodshed was only averted by the timely appearance of the British Consul, to whom the warlike Teutons surrendered, and were by him sent on board H.M.S. "Blanche" for safety.

The British section relieved themselves by writing letters to the local thunderer, the *Fiji Times*. Many and learned were the arguments of the amount of allegiance due to *de facto* and *de jure* governments. Our local supply of wisdom was truly remarkable, and it was wonderful how so much had become collected in such an out of the way part of the world. Other pacific remedies were also tried and the Levuka merchants made a deputation and waited upon King Thakombau to endeavour to show him the errors of his way. It was supposed to be strictly unarmed, but the usual foolish person was there, armed with a revolver, which managed to go off, happily without hurting anyone. But it roused the wild blood of the household brigade, who luckily in this case belonged to the regular army and were officered by white men. But they were not as yet very well disciplined, and they roughly handled the white-coated, panama-hatted gentlemen of the deputation, who fled panic stricken before His Majesty's foot guards. This episode is known in Fijian history as "The Retreat from Nasova," the latter being the suburb of Levuka where the Royal Palace was. It is said that one prominent merchant, as he put his best foot foremost, gasped out, "Tell my brother I died a Christian, and the key of the office safe is in the top drawer in my bedroom." What might well have ended in a tragedy was saved by the presence in the harbour of H.M.S. "Blanche," which, when the emeute was seen, manned and armed boats and covered the retreat of the deputation. Her commander, Captain Simpson, also issued an ultimatum to the effect that no bodies of armed native soldiery were to be allowed within the bounds of the European portion of the town.

From this state of tangle Fiji was at length rescued by the hoisting of the Union Jack. King Thakombau was presented with a cutter yacht purchased in Sydney, which was called the "Victoria," after her late most gracious Majesty, and he received a pension of fifteen hundred pounds per annum, which he lived to enjoy for nine years. Having given in his allegiance he most loyally supported the new administration, evidence of which is to be found in the despatches of the Colonial governors. He was thorough in all things. As a cannibal he was terrible and blood-thirsty; when he embraced Christianity he did so with his whole heart, and finally as a subject of the Queen he gave her his full obedience. He was a typical old-fashioned South Sea chieftain, cunning in council, brave and resourceful in war, yet simple and patriarchal

in life and habits. As an example to his people he cultivated with his own hands his own food plantations, and as becoming a chief he excelled in all things that he undertook. At the close of his life, perhaps in his simplicity he caused a certain amount of consternation to his family and spiritual advisers. His consort, Queen Lydia, had predeceased him, and when old and feeble he announced his intention of espousing a young and buxom maid. When remonstrated with he quoted King David and Abishag and was not to be gainsaid. Not only had he such an undoubted precedent, but he also had native custom on his side. The lady was his according to Fijian law and he was entitled to do as he liked with her. So he had his way, but like even as his illustrious example, he soon after was gathered to his fathers and sleeps with them in the sepulchre of his race.

A. B. BREWSTER.

## REVIEWS AND NOTICES.

**Fables and Fairy Tales for Little Folk, or Uncle Remus in Hausaland.** By MARY & NEWMAN TREMEARNE. Illustrated. (Cambridge: W. Heffer & Sons Ltd.)

WE have already drawn attention in previous issues to English versions of Hausa folk stories. But the present volume differs, we believe, from all its predecessors, in being especially designed for children's reading. The inexhaustible charm of the fairy-tale, and especially of that form of the fairy-tale which makes animals act and reason like human beings, attaches scarcely less closely to the folk stories of West Africa than it does to those of Europe, and though a good many of these stories necessarily involve conditions either of geography or of culture unfamiliar to the European mind, there is no reason why they should not win a considerable popularity in English nurseries. Should they do so it will be a striking repetition of *Græcia capta ferum victorem cepit*. From the child's point of view most of these stories possess the crowning merit that they have no particular moral. Virtue is occasionally rewarded and wickedness occasionally punished, but it is a happy-go-lucky process at best. Brer Rabbit possessed little moral earnestness, but undeniable charm of character—that charm with which Providence, for some inscrutable motive, has chosen so often to invest the scapegrace. The spider in these stories is far more of a moral reprobate than Brer Rabbit ever was, and not nearly so attractive—though his charms proved too much for the lovely Hausatu—but he generally manages to get the better of the other animals. For the child's sake we are glad, for the just resentment of children is awakened when the moral lesson whose proper home is the schoolbook and the hymn audaciously intrudes itself into the fairy-tale. Devotees of Uncle Remus will welcome the reappearance of their old friend the Tar Baby in a very thin disguise. The authors cannot lay claim to the rare literary gift which has made Uncle Remus immortal, but the stories are told with

a simplicity and absence of affectation which are welcome. The illustrations include simple drawings and a few photographic reproductions of West African scenes.

**Notes on the History of the Cayman Islands.** By G. S. HIRST, M.B., Commissioner of the Islands. (*Press of the P. A. Benjamin Mfg. Co., Jamaica.*)

Every part of the West Indian Archipelago is indissolubly connected with seething events in Europe, and Mr. Hirst has done a useful work in collecting the writings and traditions which show the part played by this small isolated part of our possessions. The Caymans have not loomed largely in literature, but they are alluded to in Scott's "The Pirate" as a place described by the worthy Bunce "where a brace or two of fellows may be shot in the morning and no more heard of or asked about them than if they were so many wood pigeons." There is certainly a strong flavour of piracy about the early history, but Mr. Hirst pleads that under the humanising influence of the islands the buccaneers generally settled down to a quiet life and peaceful occupations. The descendants of these Homeric wanderers do not appear to have produced any distinguished person so far, but the Commissioner very properly hopes for better things, and the following passage displays a spirit of optimism not unworthy of the old British confidence.

"This history, I hope, is published on the verge of a new era which I have no shadow of a doubt will ere long prove that Caymanians still carry in their veins the blood of the stolid persevering Briton, who from nothing has built up the greatest empire this world has ever known, and who means to keep it. Let Caymanians now enter with their hearts and bodies into this laudable object, let them vie with one another in building up this Dependency and thus help in building up this Great Empire. Let it be that when this history has to be written afresh, or revised at least, the name of one Caymanian will be introduced as a patriot of whom the British Empire throughout the world will have occasion to honour and hold up to the rest of the world with pride. If Corsica could give to France an epoch maker, cannot the Caymans do the same for the British Empire?"

"The tendency of the present day, however, is to denounce the British nation and scorn the patrimony one ought to be thankful for. The young men of Cayman are too fond of renouncing Britain and embracing citizenship of one of the numerous modern republics the American Continent is so notorious for. Whether any of them are of any more credit to the republic of their selection than they were to the British nation has not so far been proved. We

hope, should another edition of this history ever be published, that this stain on the loyalty and patriotism of the Caymanian will have been wiped out and redeemed by the uprising of a native of Cayman either as a great soldier, sailor, patriot, or in some other capacity useful to his nation at large."

---

**India : Eight Lectures prepared for the Visual Instruction Committee of the Colonial Office.** By H. J. MACKINDER, M.P., M.A. (*George Philip & Son.*) 1s. net.

These lectures were prepared for delivery with a set of lantern slides, which can be bought, and constitute the first instalment of a complete course of lectures on the Colonies and India. Lectures on the United Kingdom, adapted for use in different parts of the Empire, are already in the field. Mr. Mackinder's treatment of his subject is admirably adapted for the purpose. But even without the slides his descriptions are throughout vivid and picturesque. The traveller could not have in his hands a better guide, for its size, than this, and for educational purposes it is excellent.

---

### **The Imperial Department of Agriculture in the West Indies.**

A Paper on this subject, which was read by Sir Daniel Morris before the Royal Colonial Institute on the 10th of January, has been published in the miscellaneous series of Colonial Reports (price 1½d.). In this paper, the history of the Department, since its first establishment in consequence of the recommendations of the West India Royal Commission of 1897, is traced in some detail, and its work in connection with the cultivation of such products as sugar, cocoa, rice, tobacco, cotton and fruit is described. In all its activities the close interdependence of scientific research and practical work is illustrated, and the contributions of officers of the Department to our knowledge of plant diseases and insect pests, the composition of soils and manures, hybridization and artificial selection of seeds, have formed no inconsiderable part of its achievements. Another important branch of its activities has been connected with the development of agricultural education. Sir Daniel Morris pays a tribute to the readiness of West Indian planters to co-operate with the Department's work, and with reference to their reluctance to experiment with new methods and new products, he affirms that the charge against them in this respect has never been generally true, and has become less and less true in recent years. With justifiable pride he points to the manner in which the West Indian Department has been accepted as a model when the establishment of agricultural

departments elsewhere in the tropics has been undertaken. It is satisfactory that the Imperial Government has agreed in principle to the continuance of the Central Office of the Department for a further period of ten years from the 1st of April in this year.

---

**The Agricultural and other Industrial Possibilities of the Gold Coast.** By J. A. BARBOUR JAMES. (*St. Bride's Press.*)  
Nominal price 2s. 6d.

The writer, who has had considerable experience of agriculture in British Guiana, argues with force in favour of scientific training. The lesson is particularly wanted on the West Coast, where agriculture is and must be left to the native. But neither there nor elsewhere can primitive methods be nowadays successful. A good deal of information is given in a practical shape on the various tropical products.

---

The first two numbers of a quarterly review devoted to agricultural matters of interest in connection with the Congo (*Bulletin Agricole du Congo Belge*) have appeared under the auspices of the Belgian Colonial Office. The bulk of the review is written in French, but there are one or two articles in Flemish. The office of the review is at 7 Rue Thérésienne, Brussels. It should prove of interest to all connected with tropical agriculture in Africa.

---

We have received "A Guide to the Flora of Gibraltar," by B. H. T. Frere (Gibraltar Garrison Library), which will be found very convenient by residents or visitors who interest themselves in the botany of the place.

---

The "Writers' and Artists'" Year Book, 1911, published by Messrs. A. & C. Black (1s. net), would be of help to those who have to order English Magazines from the Colonies, as the subjects and prices are given. The last seems a very complete one, and an account is added of American journals.

## BUSINESS NOTES.

THE figures of the foreign trade done by the United Kingdom in 1910 are very satisfactory. In the decade 1900-1910 the export of British goods increased by 47 per cent. in value, though on the whole prices were lower at the end of the period. This excellent position is largely owing to the investment of British capital in other countries which produce food and material for manufacturers. These investments represent part of the capital which is put into the country's industries, and it is certainly better that money should be applied in this way, though "going out of the country," than on luxuries or purposes which are not remunerative. The greater part of the capital goes to the safe side of foreign development, the public loans, the railway and public works; but money is never lacking for any concern which is or can be made to appear promising, and every year seems to see an increase in the City of companies, great and small, formed for every exploitation in the colonies and foreign countries. This growth creates a demand for directors of reputation, and the retired colonial civil servant is very much in evidence, a fact which, we may fairly assume, is some tribute to the ability and integrity of the service.

The renewed boom in rubber indicates an expectation of the maintenance of the price for some time to come. The world's consumption is now calculated at 100,000 tons; of this the Middle East supplies about 8,000, but by 1915 it may supply about 100,000, equal to the present consumption. The price, therefore, must fall eventually, unless the consumption increases substantially. But 1915 is a long way off from the point of view of the Stock Exchange speculator, who gathers his harvests as he may.

Since the beginning of 1908 the value of fine hard Para rubber from South America, which forms the market standard, has fluctuated from 2s. 9d. per lb. in February of that year to 12s. 6d. per lb. in April, 1910. Lately it has fallen to about

6s. per lb. There do not appear to be any signs at present of such increased demand as would send up the price when the increased yield has told, and having regard to this increased production a gradual fall may be expected during the next few years. At 3s. it might not be profitable to extend operations in South America, and at some such point history would repeat itself and the market would go up.

It should be observed by producers that smoke-dried rubber commands a premium as the process has a preserving effect, so that the article stands handling better and the inevitable deterioration is put off. The less handling done on the plantations the better, so long as the impurities are washed out. Crepe is often now rolled out thin to hasten drying, but it should not be reduced to less than one-eighth of an inch thick.

To some extent rubber has displaced tea on the plantations, and as the demand for this product expands steadily, it is likely enough that the tea planters will see good times.

The growth of maize is striking, and is likely to be more so if it can be established, as stated in America, that it can compete with sugar cane and beet as a sugar producer. It also produces alcohol and paper pulp. It is claimed that it yields, per acre, 2,850 lbs. of sugar, 388 gallons of alcohol, and 4,050 lbs. of paper pulp. The immediate effect of these expectations is to limit the production of cotton, which is grown in the same districts of America. This fact should help on the industry in such countries as East Africa and Nyasaland, where it could be produced on a good scale.

---

### Oil.

The Annual Report on Trinidad and Tobago for 1909-10 contains some interesting particulars with regard to the Colony's oilfields. Boring for oil was actively carried on during the year by the New Trinidad Lake Asphalt Company and the Trinidad Oilfields Company. The former company has given evidence of its belief in the stability of the oil industry of the Colony by the erection of two large iron tanks with a storage capacity of over two-and-a-half million gallons (64,000 barrels) each of which is connected with settling reservoirs into which the oil flows from the wells. In the case of one well, the oil has been running for some months into a reservoir by natural gas pressure and without pumping. A pipe-line of 10-inch diameter has also been laid from the storage tanks to the sea, and has been carried out on a special jetty built alongside the company's main pier (which is 1,700 feet in length) into deep water with secure anchorage for ships. Boring is also being carried on at Guayaguayare (General Petroleum Properties Limited) and Palo Seco (Petroleum Options Limited). In all cases the furnaces are fed by oil fuel or by natural petroleum gas. At La Brea the boring

area at present being developed is within  $1\frac{1}{2}$  miles of the village, and barracks have been erected in close proximity to the wells. At Guayaguayare and Guapo bungalows and barracks have been erected for the employees. At the former place a tramway has been laid down from the beach to the works, and at the latter a railway and jetty are, at the date of writing, in course of construction. An aggregate of 5,927 feet of borings were drilled during the year. The total aggregate within recent years over the various oilfields is about 18,000 feet. Generally speaking, oil was struck at fairly shallow depths.

There is every likelihood that the oil industry will before long contribute materially to the resources of the Colony, though for the present there is some slackening of the market activity in this direction.

There is some reason to think that the oil-bearing strata of Trinidad pass into Venezuela through a part of British Guiana, and two applications have recently been made for prospecting licences. These have been granted, but leases cannot be issued until provision is made for them by law.

The Newfoundland Government has granted 80 square miles for oil working without any royalty.

Perhaps the most serious question with regard to oil is that of monopoly. The industry is at present largely in the hands of two companies, the Standard Oil Company and the Shell Company, both of which are exceedingly active. It is said that the latter body is part of an organisation in which the Royal Dutch Company has a large interest. It is conceivable that in a short time the world's supply may be controlled by companies which are not under British influence. Having regard to the naval importance of the article, it is essential that care should be taken to secure that any bodies exploiting oil in the Crown Colonies should be really of British character.

---

### Tin.

In Northern Nigeria the activity of the prospectors for tin has been considerable, and numerous companies have applied for licences and leases. The price of tin during 1910 rose from £153 per ton to £190. This was due to a considerable falling off in the supplies from the Straits Settlements, caused largely by the transfer of labour to the rubber plantations, and to the demand for the tin plate in America, and probably a high price will on the whole be maintained. Much of the Bauchi ground is of proved richness, but the mineral has been found mostly in shallow deposits in river beds near the sources of the streams, and doubts have been expressed whether these will be of long life.

The construction has been arranged of a branch of the Baro-Kano railway to the Bauchi highlands as far as Leri, the Treasury finding the money on a guarantee by the Niger Company to meet half any deficit for ten years. The estimated cost is £200,000, and £10,000 have been provided for the period ending on the 31st of March this year. It has been decided that the gauge shall be 2 ft. 6 ins.

---

### Ramie.

This product has so far been very disappointing. It has some indubitable virtues. It is the strongest of all fibres; its filaments are very long, fine and soft. It can be spun into yarns of all kinds, and can be used by itself or mixed with other substances. But as a rule the companies which have been formed to exploit it have entirely failed to fulfil expectations. The explanation is fairly clear. In many cases the selection of land was unfortunate, but the chief cause of failure was the imperfection of the machinery. The decortication of ramie is a simple matter, but the difficulty is that the dried juices of the ramie stems are very gummy. When these juices are exposed by decortication to the air, they are oxydised, like a slice of an apple, and the dried juices cling tenaciously to the fibres. In this state it is obviously exceedingly difficult to remove them, but unless this is done the fibres will not pass through the teeth of the combs, except with a good deal of tearing and damage to the yarns. It is necessary to avoid this mischief to remove the juices before they dry and harden. This must be done during, and not after, the decorticating process. A proper washing of this sort reduces the weight of the produce by about 30 per cent. It is said that by the new machinery designed for this purpose the cost of degumming is about 1½d. per pound, and of course there is a great saving on the freight when the process has been carried out.

---

### Sisal.

There is no doubt that in suitable situations and with good management large profits can be made out of this product. The following calculation has been made on behalf of a company with a small capital which is operating in the Caicos Islands. The cost of leaves bought from the natives is put at £4 per 1,000 bundles of 50 leaves each, and of extraction, barking and baling at £2; with freight to New York and agent's commission there at 2½ per cent., the whole outlay figures at £9 10s. This quantity should give one ton of dry fibre delivered at New York, where the price is £23 to £24. This represents a margin of profit which should satisfy anybody. The company in this case can also make a handsome profit from its store, to which much of the money paid to the natives comes back. The cost of production should be less eventually when the proprietors use their own leaves.

The sisal plantations in German East Africa are paying high dividends, up to 80 per cent., and enterprises in the British territory should do well.

---

### Decorticating Machinery.

The *Queensland Agricultural Journal* gives information concerning several large types of these machines, such for instance as are capable of cleaning from 40,000 to 150,000 sisal leaves per day of ten hours, with six men to attend to the machinery. The examples of these that are mentioned are the Prieto, the Todd, the Finnigan-Zabriski, and the Ajax, which is of British make. These are not suited to small plantations, although an instance is given of a Finnigan-Zabriski machine, which is producing 1 ton of marketable fibre daily, in use on an estate of 60 acres. The cost of the best machines is as much as £600, including freight and other expenses. They are also costly in that the power for driving them ranges from 50 to 70 h.p.

Efforts are being made towards the production of lower-priced automatic machines. One of the latter is the Irene No. 51, made by the Prieto Company, which requires 12 h.p. and which has an output of 20,000 to 30,000 cleaned leaves per day. The cost of this is £300, f.o.b. London.

The same journal states that, of the British made machines, the automatic Ajax is stated to be a perfect, low-priced machine. This does not require more than 15 b.h.p., as it is a single-drum machine, with an output of about 2,500 to 3,000 leaves per hour. It weighs  $2\frac{1}{2}$  tons net, and like the Irene, it is suitable for plantations having an area up to 200 acres; it produces  $\frac{1}{2}$  to 1 ton of fibre per day, according to the character of the leaves. The machine is made by the Alma Machine Works, Liversedge, Yorkshire, and sold by Messrs. Walter Griffith & Co., 6, Crosby Square, London.

---

### Cotton Growing.

It appears from a Ceylon report (M. 38, 1910), that Indian cotton can only be regarded as a paying crop by the small proprietor who puts his own and his family's labour into it. No one could put costly labour into it and make it pay. But Mr. J. S. J. McCall, Director of Agriculture in Nyasaland, while on a visit to Ceylon, furnished a report prognosticating a great future for cotton in the dry zones of the Island provided the water is conserved and distributed. There is certainly a great amount of land available for the purpose, but while rubber is booming it is hopeless to expect that capitalists will take up cotton. Other products, too, such as tea and cocoanuts, pay better. The best chance for cotton in such a place is as a catch crop amongst young cocoanuts.

The following clear directions are given in the report for the guidance of planters:—

“Before picking the crop, arrangements must be made for getting seed for the following year, and selection of the seed *must* be carried on; otherwise the crop will rapidly deteriorate from year to year, and in a few years' time the Sea Islands will be only of the quality of Uplands and fetch perhaps 6d. a pound. The fields should be carefully gone over, and the best bushes marked by tying a red rag to them. The main qualities to be attended to are length and silkiness of the fibre, and a three-inch measure should be carried. No seed whose fibre is less than one-and-a-half inch should if possible be taken. All the pods on one bush tend to be nearly alike, so that examination of two or three of them is sufficient, and if they are found to be good enough the bush may be marked and all its seeds taken. To estimate the length of the fibre, a tuft should be pulled out by the finger and thumb of both hands, placed side by side across it, and then the two portions of lint put together and pulled again, and so on. It is found that a rough estimate of the crop to be obtained may be got by counting the bolls or pods on a bush, and if there are 15 bolls on bushes 20 inches apart, in rows of five feet apart, the crop of lint may be estimated to be 100 lbs. an acre. Or, in other words, about 80,000 bolls give 100 lbs. of lint and 200 lbs. of seed, so that 2,600 bolls or 175 plants at 15 bolls to a plant will give enough seed to plant an acre. These plants should be marked and coolies paid extra to pick only the seeds of these plants and no others, and this seed should be ginned separately, and, in fact, if there be enough, should be baled separately, as its lint should be of better quality than that of the rest of the fields and should fetch a higher price. Great care must always be taken to keep each bale of uniform quality.

“The cotton may now be picked, before it has begun to fall. The pickers, who may be paid a cent a pound at first, should be provided with canvas bags about two feet deep and 18 inches wide. In picking Sea Island cotton the very greatest care must be taken to get it perfectly clean, without any stains of earth, and without any bits of leaf or other dirt clinging to it. Any cotton brought in dirty must be thoroughly cleaned before the picker is paid. The least dirt or admixture of leaf may lower the value a quarter. Picking should be done with both hands, the boll being held with the left hand and the cotton cleanly removed in one mass, at one operation, with the right.

“When brought in the cotton should be spread out thinly in the sun for several hours to dry, and then if necessary should be whipped, *i.e.*, threshed against a grating of wire netting ( $\frac{1}{8}$ -inch mesh) about three feet by two feet, in a wooden frame; the dirt, sand, etc., passes through. One man should be able to whip about 300 lbs. a day.

“Sea Island cotton must be ginned in a roller gin, and the usual gin employed is the Macarthy double action roller gin, whose roller should be made to turn at about 160 revolutions a minute. A Hornsby Akroyd oil engine of two-and-a-half horse power has ginned all the cotton grown on 60 acres at Maha Illuppallama, and could have done twice as much if necessary.”

With the above may be compared the following directions issued in South Africa:—

“The seed must be planted in hills or ridges. The distance between the rows and the plants in the rows depends very much on the land and the kind of cotton grown. It is recommended that Sea Island cotton be planted in rows six feet apart and two feet apart in the rows, whilst in the case of other sorts the rows are only four to five feet apart and the plants 18 inches apart in the row. The actual distance, however, is a matter which only local experience can satisfactorily decide. About 10 to 12 lbs. of seed is required per acre, according to the variety, say, 10 lbs. Sea Island and 12 lbs. Egyptian.

“In each ‘hill’ put about four seeds an inch deep, which should germinate in four or five days. As soon as the young plants are about a fortnight old, pull out the weaker ones, only leaving the two strongest ones in each ‘hill.’ A fortnight later still, the weaker of the two remaining plants should also be pulled out, leaving the stronger only. At this time any blanks, if such there be, in which the seeds have altogether failed to germinate, or which show signs of weakness, may be replanted with the most vigorous plants removed from other ‘hills.’

“On level, or nearly level grounds, it is not necessary to throw up ridges to plant the seed on, but in slopes it would be advisable to do so, about six inches high, and as nearly level as possible, in order to check the flow of water during heavy rains.

“When the plants are about eight inches high, and again when from 12 to 16 inches high, they should be ‘moulded up.’ The land should be kept free from weeds until the cotton plants cover the ground sufficiently to prevent the weeds from growing, but no weeding should be done after the ‘bolls’ or cotton pods begin to form.

“A cotton plant should be low and compact, branching near the ground, and should have small close-pointed limbs and a large number of ‘bolls.’

“In about five months (depending on climatic conditions) after planting, the first ‘bolls’ will begin to open, and if the plants are properly cared for they will keep on fruiting and opening for four months or so. Cotton should only be plucked out of the ‘bolls’ when the latter are fully opened, but it must not be left on the plant any longer than is unavoidable after this occurs. The art of picking

cotton is quite an easy one to master, and the labourer soon becomes expert and rapid, picking readily 100 pounds per day. The 'boll' or case should be held firmly with the left hand, and the whole of the cotton (of course including the seed) should be removed by the right hand with one pull. In order to have both hands free each picker should be supplied with a canvas bag two feet long by 18 inches wide, made to hang from the shoulders, and which should be divided into two divisions for first and second grade cotton. He is then enabled to remove anything in the shape of leaves, etc., which may possibly adhere to the cotton, before dropping it into the bag. This is easily done at that time, but will be found much more difficult afterwards. When the bags are full they should be emptied into a sheet or large basket placed at the end of the rows where there should also be some contrivance to cover up the cotton in case of rain.

"Except in very dry weather it is advisable to spread the cotton for a little in the sun after picking, and this is absolutely necessary if the cotton shows the least sign of dampness, as it is then liable to heat and to become discoloured, and deteriorates much in value after being packed. It cannot be too strongly impressed on the planter that everything that stains, discolours and dirties the cotton in any way tends greatly to lower its market value. In determining the value of a sample, cleanliness and good colour come only second to silkiness and length of staple, in fact, dirt and stains will enormously reduce the price of otherwise splendid cotton."

Mr. Barbour James in his book on the Gold Coast deals with the subject as follows:—

"Where the tendency is to produce much growth, a greater distance must be allowed than where the habit of the plant is smaller; in other words, the poorer the land the less the distance. There can be no doubt that cotton planted in rows sufficiently wide apart to allow the sun to enter freely is less liable to disease than cotton planted closely, and much less likely to suffer severely from attacks of worms. The latter delights in dampness and shade, both of which are induced by close planting. There are minor differences in various countries, yet the principal point aimed at is always to get the same, viz., to get deep tilth to get the cotton roots to go deeply into the ground. The cotton plant has a tap root which will, under favourable circumstances, go three feet down or more into the soil in search of food and moisture. The deeper the soil is stirred the deeper the roots will go; and consequently the greater the feeding area. By the operations of culture already mentioned, the soil is left in a loose friable condition, very suitable for the reception of seed. As the land is left fallow some time before cotton planting to enable the ordinary atmospheric agencies to act upon it, the soil does not turn up in that lumpy condition, but is in such a condition that

in passing the plough between the furrows the earth is easily thrown up to form the ridges, and falls naturally from the sides in a finely-divided state. High beds are in favour, as they promote drainage. If manure is used, there is no reason why cotton may not continue in continuous cultivation. The land having been properly prepared, operation of planting now begins. This depends on climatic conditions. From the middle of March to as late as May 1st, seed should be sown shallow and early, for as the soil is much cooler then, the seed has, when not planted deeply, more warmth for germination.

“Planting is done on the top of the beds. A shallow furrow is first opened on the top of the bed, about two or three inches deep; the seed is deposited and covered by one or two inches of soil. In some countries these operations are carried out by what is described as a ‘cotton planter,’ which is drawn by a mule in a similar manner to an ordinary plough. A man and a mule can accomplish as much as from six to eight acres a day. A small cultivator would not employ a ‘planter,’ but he opens a furrow on the top of the ridge and deposits the seed through a tin tube about five or six feet long, with a funnel at the upper end. The seed is carried in a bag suspended around his shoulder, and the tube is fed by the hand through the funnel, the lower end of the funnel resting in the line where the seed is to be deposited. The seed is subsequently covered by drawing a harrow—a wooden block or board—over the land. On very rich land, where only very little manure is employed, the seed and manure are sometimes deposited together. Originally, planting was done by opening the places in the ridge with a hoe or cutlass at more or less regular distances, the seed dropped into each hole by female labour, accomplishing one acre per day each woman. With the ‘cotton planter’ seeds are deposited one inch apart in the row, the plants being subsequently thinned to the required distance. The question of selection of seeds for planting is one of very great importance; in fact, it is one that cannot be over-estimated. The choice of good seed is an essential to the production of good staple cotton. Transplant when four weeks old; in about seventy days first flowers appear, seventy more the bolls open. At this time the plant is about four to five feet high. Moulding and ploughing should be undertaken when six weeks old; guinea corn or peas planted to stem the wind.”

Instructions are also given in the report of the Director of Agriculture in Nyasaland for 1909-10. Satisfactory progress is being made here, and the quality of the cotton is very good. In a few years, it is believed, native-grown cotton will form the largest export of the Protectorate, and the British Cotton Growing Association will find an excellent field there for their ginneries.

In Nyasaland, where the growing season is short, the branching character of the plants has a great influence on the ripening of the crop, and therefore the yield per acre depends in no small degree on the type of plant grown. It is necessary, therefore, to take advantage of every character that leads to early ripening, and the heaviest yields are obtained from plants which, though carrying many fruiting lateral branches, arranged round the main stem in such a manner as to allow the maximum amount of sunlight to reach the entire plant, yet do not unduly shade their neighbours or obstruct the necessary tillage operations. Plants with very long horizontal or prostrate lower branches should be avoided, as they interfere with cultivation; if they are fruiting branches the lower bolls open late and the cotton is liable to be stained by the soil; if they are purely vegetative branches they receive insufficient light for maximum assimilation. Plants with dense upper foliage should also be avoided, as they generally shed a large percentage of their lower bolls.

It might be thought possible to obtain as good a yield from a few large plants as from a greater number of smaller plants; this may be true in a country with a very long growing season, but in Nyasaland the season is too short to mature large plants. In the experiments so far made the Director finds that branching character is to a great extent handed on from parent to offspring and is not influenced by the nature of the soil. Thus plants of the same parentage grown on sand and clay soils showed similar modes of branching, although the plants on the sand were only half as high as those on clay. Once a type is selected from acclimatised seed, branching character remains practically constant in the offspring of Upland cottons. Egyptian cotton is generally much more influenced by change in climate than Upland cotton, especially as regards branching character; the decreasing crop of Nyasaland-grown Egyptian seed is attributed in large measure to the increasing percentage of tall scarcely-branched plants; in practice cultivators of Egyptian cotton in Nyasaland prefer newly-imported seed. If Egyptian cotton were carefully selected, after being grown in Nyasaland for a few years, it is believed that it would give better results than newly-imported seed, and confirm experience in the United States, where the crop was at first pronounced a failure, but where, after five years' selection, Abassi cotton gave a yield of 460 lbs. of lint per acre.

---

### **Turtles and Sponges.**

The New York market, of course, deserves special study in the West Indies, and there are various possibilities which are well worth considering. Thus attention might be given to the breeding of the green turtle and the shell turtle, commonly called "Hawksbill."

These turtles have been raised in Lake Katherine in the centre of the Caicos, and have done very well in past years, and when the people who raised them left the Island, large numbers of the turtling boats landed and cleared the lake of all the turtle. There are still, however, a few turtle left in the lake. The green turtle grows to marketable value (60 to 80 lbs.) in three-and-a-half years, this being confirmed by the rate of growth observed in both wild turtles and any hatchings in captivity. A female turtle will lay 500 to 600 eggs in a season, and from experiments made by others in the adjoining islands, about 65% of the eggs set have been hatched, and it has been proved that green turtle can breed in captivity. Hawksbills do not mature so quickly as green, taking six to seven years to make a five to six pound shell. The value is, of course, weight for weight, much higher than green. The shell has been taken to average 24s. per lb. for good seconds. Green turtles are worth 9d. to 10d. per lb. live weight in New York wholesale, and consequently an 80 lb. turtle would bring £2 10s. to £3 10s., less commission on sale, and ½d. per lb. freight from Turks Island to New York. There is no duty on turtles in the United States. When green turtles are ready for shipment, the profit for 1,000 of these annually can be reckoned at £2,000, and 1,000 Hawksbills turtle annually at £5 each, which return should be available in six years from the date of hatching. The bottom of the lake is, for the most part, a fine white sand, overlaying coral limestone, and carries a large part of the grass ulva on which the green turtles feed, while there is sustenance for Hawksbills in the shape of fish, zoophytes and molluscs.

There is another source of income with very little outlay, viz., the raising of sponges. Experiments in this industry have already successfully been carried out, the Caicos Bank being one of the world's great sponge fisheries, producing both sheep's wool and reef sponges. The sponges obtained on the banks at present run small, owing to the operations of the negro fishermen, who give them no chance to grow to their proper size. The United States Fisheries Bureau estimate sponge profits nett, in four years, at £160 per acre. Expenses are estimated at £40 per acre, and the method adopted of raising these sponges is to cut up a live sponge, attaching the small pieces to slips of cement with aluminium wire, when the sponge will grow readily, having a flat bottom, and this class of sponge commands the biggest price.

---

### Milk and Mutton.

On the New York market the milk from the fruit of the Papora trees fetches, dried, about 10s. per lb. The cost of preparation is very small, and the tree fruits in two years after planting from seed.

On the other hand the West Indies could take supplies of mutton and possibly, some day, the intercourse of our colonies will be augmented by some enterprising combination which will take mutton from the Falkland Islands, in which favoured region it is sold at 2d. per lb.

---

### Uganda Forests.

There have been several applicants recently for leases in the Budonga Forest, a dominion situated in the Unyoro Province in the neighbourhood of Lake Albert and containing, on a cautious estimate, 160 square miles. It contains a vast number of rubber trees and vines, the most important species being *Funtumia elastica*, one advantage of which over Para is that it yields a much larger quantity of latex at a single tapping. Large forest trees abound, many with clear erect boles 80 to 90 feet in height and six to seven feet in diameter; these are generally of the mahogany class. But at present the exploiters think only of the rubber and the big trees are merely in the way. There are no practicable means of exporting to Europe. Nevertheless, the timber is a great asset, and it will be sound policy to reserve it for future requirements. It could be floated from the lake to Khartoum, except for a distance of 120 miles covered by the rapids, and before very long a market may be available in the Sudan and Egypt.

---

### Magadi Soda Concession.

£1,250,000 of the Company's capital (£1,312,500) have been subscribed, being all the ordinary shares, and the Company have exercised the option given to it. The enterprise will now go on, and it will be very interesting to follow the commercial working of this unique natural treasure. The principal difficulty at the outset was that of ensuring that the market would buy the soda from this source, there being strong interests against the addition of this enormous supply, but the promoters are no doubt prepared to overcome any opposition of this kind.

---

### Castor Oil.

The castor oil bean is indigenous in East Africa, and a sample has been sold in this country at a fairly satisfactory price. It would probably repay cultivation. There would be a good market for it on the South African railways.

---

### Jamaica Government Buildings.

The Kingston earthquake of January, 1907, destroyed most of the large buildings, and the Governor attacked the task of reconstruction with characteristic vigour and expedition. The

result appears in two buildings, the General Post Office and the Treasury, and the King's House, the Governor's official residence. The architectural character selected by the architects, Messrs. Nicholson and Corlette, has met with some criticism, as is inevitable in such matters, but it is obviously well suited for tropical conditions, and will no doubt be better appreciated when it has become more familiar. Very large verandahs and colonnades are provided. The roofs are flat as offering the least resistance to hurricanes, and made in reinforced concrete, covered with several inches of gravel as a protection against the sun. The buildings are practically monolithic, the principle being to have a general raft in reinforced concrete of slabs and beams uniting the footing of the walls and pillars. The new Law Courts are being built by contract of Messrs. Mais and Sant, of Kingston. In all the cases the Coignet system is adopted. This employs plain round bars of mild steel, the pillars being constructed of vertical bars bound by spiral hooping of small diameter.

---

### Wireless Telegraphy.

Messrs. Preece, Cardew and Snell have made observations as follows upon the question of telegraphic communication between Nairobi and the Northern Frontier of the East Africa Protectorate.

It is difficult to express a definite opinion upon the cost of establishing and maintaining communication by means of ordinary telegraph lines or by means of wireless telegraphy in East Africa, without an intimate knowledge of the actual country. A land line is, generally speaking, preferable to wireless telegraphy. The apparatus required is very simple, and well understood. The attendance is not necessarily highly skilled, and the cost of maintenance of the apparatus is trifling. In the case of wireless telegraphy, the two installations provided with apparatus are in communication with each other only, whereas with telegraph lines, stations can be inserted at any point along the route, and anyone travelling thereon can maintain constant touch with headquarters either by means of telegraphy or by telephone. The maintenance of wireless installations is highly technical, and the apparatus is of a more complicated character.

The plant required for a wireless station of 5 kw. capacity, capable of working over about 300 miles of sea, such as is now being supplied to Fiji, consists of the following :—

PLANT:—A 10 h.p. oil engine, alternator, motor generator, storage battery, and switchboard.

TRANSMITTING APPARATUS:—Transformers, keys, adjustable inductance coils, controllers, main condenser, adjustable condenser, rotary spark gap and jigger.

RECEIVING APPARATUS:—Aerial, adjustable inductance, adjustable condensers, detectors, telephone and sundry testing apparatus.

The aerial itself will consist of five masts, one being 160 feet high and four 50 feet high, and a quantity of bronze wire is stretched between the poles, forming a carpet insulated from earth by means of special high tension insulators.

Wireless stations also require a considerable supply of stores. With an oil engine, it will be necessary to provide a good many gallons of oil per day, according to the use to which the station is put, and the supply of oil would be a matter of considerable difficulty to an isolated station, and require the maintenance of a road of communications which might be as expensive to keep open as a land line. It may be possible to use small boilers and steam engines, providing there is an available supply of wood within easy reach of the frontier station, but the matter is one which requires careful local consideration.

Experience at present with commercial wireless telegraphy overland, especially in the tropics, is limited. We believe that there are only two stations working successfully over a distance exceeding 400 miles, namely in Brazil, where communication is maintained between two towns about 500 miles apart. In this case, it has been necessary to have plant at each station having a capacity of about 70 h.p.

The successful operation of wireless telegraphy depends largely upon the type of country which is served, and it is not possible to state definitely that communication can be maintained under all circumstances with any particular plant. The matter must be the subject of experiment. The chief difficulty is due to atmospheric disturbances, which apparently vary in every climate, and they might be so bad in the district under discussion, that communication would be difficult to maintain. Rough experiments recently made in Southern Nigeria shew that atmospheric disturbances occur which would probably render wireless telegraphy difficult through the greater part of the day. Experience with the telephone service in Uganda also shews that considerable electrical disturbances occur there during the daytime. Of course, such disturbances would not necessarily interfere with communication during the whole of the 24 hours, and it is quite possible that there would be no difficulty in maintaining communication for a few hours daily with some regularity.

Assuming, however, that wireless telegraphy is possible, the following estimate may be given of the probable cost of two installations, which should be capable of maintaining communication over 400 miles of land. The plant proposed would consist in each case of a 25 h.p. oil engine, and a 15 kw. dynamo and other apparatus. This plant is capable of communicating over the sea for a distance up to about 800 miles. It would be necessary to provide 6 masts at

each station, two of about 250 feet high, and the others about 150 feet high. The cost f.o.b. for each station would be approximately as follows:—

6 Masts	...	...	...	...	...	£1,200
Oil engine, dynamo and other apparatus	...					3,000
						<hr/>
Total	...	...	...	...	...	<u>£4,200</u>

The cost therefore of the two stations would be approximately £8,400 delivered f.o.b. London.

With regard to the cost of a land line, it is understood that at the present time telegraph lines extend as far as Fort Hall in the direction of the Frontier, a distance of 50 miles, so that the additional land line would be approximately 350 miles in length. The cost of the materials for a line consisting of iron poles, iron wire and apparatus of the best type should not exceed £22 per mile f.o.b. The total cost therefore of the land line would amount to about £7,700. The cost of transportation and erection of the wireless stations and of the telegraph line cannot be estimated by us with any degree of accuracy. The cost of transporting and erecting a land line has been put approximately at £18 per mile, and on this basis, 350 miles would cost £6,300. The cost of transporting and erecting the wireless stations should not exceed this figure.

Upon the above basis, it would appear therefore that the capital cost of providing two wireless stations is likely to be very similar to the capital cost of a land line.

As regards the annual cost of working the above installations, in the case of wireless telegraphy, it would be necessary to provide at each station one white man in charge who would be skilled in wireless telegraphy, one Indian telegraphist, and two Indian mechanics to look after the mechanical details. Assuming the white foreman is paid £400 per annum, and the Indians £120 per annum each, and allowing a sum of £340 for fuel, stores, etc., the total cost will be approximately £1,100 per station. There would be, in addition, certain costs for supplying rations and stores to the isolated station.

With regard to the land line, the staff required would consist of two inspectors at £250 per annum, two Indian telegraphists and two linesmen at £60 per annum, and fourteen native patrol men at £15 per annum. Assuming the cost of keeping the bush clear would be about £200 per annum, and stores are £100, the total annual cost of maintenance would be about £1,250.

There can be no doubt that installations of wireless telegraphy in difficult countries, such as the East African Protectorate, might be of considerable service, and on the whole the proper course to be adopted would be to erect a small wireless installation of 5 kw. capacity, using a long wave, at Nairobi or Fort Hall, and a similar station

temporarily at about 200 miles towards the Frontier. This should at any rate reduce the lines of communication between the Frontier by that distance, and enable something to be done towards keeping up communications. Careful experiments could be carried out, and if it is found that communication can be relied upon with a 5 kw. plant over this distance, additional plant could be added to the Fort Hall station of sufficient capacity to ensure communication up to a further distance, or if the experiments justified, for the full distance of 400 miles.

The cost of two complete plants of 5 kw. capacity delivered f.o.b. would be approximately £3,600, but if the storage battery and motor generator be omitted, which might be done in the first instance, the cost f.o.b. should not exceed £3,000.

---

### Linotype.

The details of this composing machine are fully set out in printed pamphlet, but it is sometimes enquired what amount of skilled labour is required. The machine, though apparently full of intricacies, is really very simple to operate, and all the parts are very accessible. It is claimed that in England, with ordinary intelligent but not specially skilled labour, the machine will do the work of six skilled compositors. But in India it is found necessary to have a white overseer, and this would usually be the case where native labour is employed. One machine requires one quarter horse power to drive it. The type-metal pot can be heated with oil or gas; unless otherwise specified a gas burner is always supplied. The type-metal is specially made and must be procured from the Linotype Company. If a machine is ordered it is prudent to get an extra magazine of matrices.

---

### Aero and Motor Boat Exhibition, Olympia.

Some complaints were made in this country when a Colonial Government ordered motor boats from Holland, but at that time this country was undoubtedly behindhand in this industry. It is to be hoped that this exhibition will show the advances which have been made since. Messrs. Thornycroft, who have made substantial reductions in price, exhibit the following:—

1. The new (M/1) type Thornycroft single-cylinder  $4\frac{1}{2}'' \times 6''$ ,  $7\frac{1}{2}$  b.h.p. paraffin Marine set, with reversing gear, shafting, stern tube and propeller.

This set shows the greatest departure from previous practice in the very compact and ingenious arrangement of the reversing clutch which is contained in and forms part of the flywheel. Another

point is the single lever control. The general simplicity of the equipment should particularly appeal to those who are interested in a small power auxiliary set.

2. The M/2 Marine set, two cylinders,  $4\frac{1}{2}$ "  $\times$  6", 15 b.h.p. on paraffin, with Thornycroft reversing and stern gear.

3. The M/4 Marine set, four cylinders,  $4\frac{1}{2}$ "  $\times$  6", 30 b.h.p. on paraffin, with Thornycroft reversing gear.

4. The C/4 Marine set, four cylinders, 6"  $\times$  8", 47 b.h.p. on paraffin, with reversing and stern gear.

This latter set embodies many notable improvements, among which may be mentioned the special automatic lubricating arrangements. The control for all practical purposes is by single lever, thus simplifying handling.

This type has been very largely adopted for auxiliary purposes in large yachts, among which may be mentioned Col. Courtenay Morgan's "Sylvana" (R. Y.S.), and Mr. Tom Sopwith's "Neva." It has also proved its worth in East Coast fishing vessels and barges, such as the "Rocklight," owned by the British Petroleum Company. Thirty-six sets of the six-cylinder size are now in hand for orders for boats for one European government.

5. P/4 type, four-cylinder, 4" diameter  $\times$   $4\frac{3}{8}$ " stroke, complete with reversing and stern gear. This engine is one of the series of light engines Messrs. Thornycroft have found it necessary to list to meet the demands of an engine which is more suitable for fast boats than their heavier or commercial type M engines. It has been fitted with success into a large number of river pleasure craft where shallow draught is essential, and also into some fast launches of the "Gyrinus" and "Miranda" types. It is designed to give 20 b.h.p. on petrol.

6. Thornycroft  $7\frac{1}{2}$  b.h.p.,  $3\frac{1}{2}$  kilowatt motor dynamo set.

7. A very handsome Solent Cruising Thornycroft Launch for Col. Cowper-Essex. This boat is of a class which should appeal to all those wishing for a boat of high speed, comfort and safety. It is fitted with a Thornycroft 30 b.h.p. light type petrol motor, and will have a speed of from 18 to 20 miles per hour.

---

### Waterproofs.

A good deal of trouble is experienced with these articles in hot and wet climates as rubber perishes and oil-skins stick. The manufacturers of "Pegamoid," which contains no rubber or other article likely to deteriorate, have been making experiments with a view to using this material for the purpose, and also for ground sheets and the like. If they succeed, the cheapness and durability of the material will make it a formidable rival to rubber goods.

### Universal Time Watch.

A watch has been put on the market which gives the local time and also the time at the principal places in the world at a glance. It is specially adapted to keep accurate time in any climate. It should be useful in offices which have to send and receive cablegrams, and the price, 22s. 6d., cannot be considered high.

---

### Hints for Collecting and Drying Plants.

In preserving plants for permanent collections, the object is to prepare specimens in such a manner that they may be thoroughly dried, the colours as far as possible retained, and such a degree of pressure given that they do not curl up in drying. For this purpose a quantity of paper is necessary, brown or stout grey, moderately absorbent, of ordinary demy size (17 inches by 11 inches) when folded.

Two boards (or better, stout frames of wire grating) are requisite, of the size of the paper, one for the top, the other for the bottom of each mass of papers. Pieces of millboard placed between the papers, if the specimens are numerous, or particularly thick, or woody, are very useful. For pressure, nothing is better than a heavy weight on the topmost board, or, while travelling, two leathern straps and buckles to bind the boards and papers transversely. Thus provided, gather your specimens—if small, root and stem; if large, cut off portions of the branches, a foot or rather more in length, always selecting those in flower and in a more or less advanced state of fruit. Long, slender plants, as grasses, sedges, and many ferns, may be doubled once or twice. Place them, before they wither, side by side, but never one upon the other on the same sheet, taking care that the thick parts of the specimens are, as far as possible, distributed to different parts of the sheet, and lay over the specimens one, two, three, or more sheets of paper, according to its thickness or the thickness of your plants; and so on, layer above layer of paper and specimens, subjecting them then to pressure. In a day or two, according to the more or less succulent nature of the plants, or, to the nature of the climate, remove them successively into fresh papers till the moisture is absorbed, and dry the spare papers in the sun, or by a fire, for future use.

Circumstances permitting, succulent plants should be placed in a separate press, otherwise the complete drying of others is retarded. When practicable, very delicate flowers should be separately dried and preserved in blotting, or other soft paper and subsequently added to the specimen of the rest of the plant.

When sufficiently dry, the specimens should be put into papers, one sheet (more if the specimens be thick) between each layer of plants; and thus a great many may be safely arranged in a small compass, and are ready for transport, covered with oil-cloth or packed in boxes. Mosses, and other cryptogamic plants, may be generally dried in the common way, those which grow in tufts being previously opened out, so as to form neat specimens. Most seaweeds require a slight washing in fresh water, and the more delicate kinds should be floated out on sheets of writing paper before being subjected to pressure.

---

### Local Sales.

Most colonies will find it very much to their advantage to provide free or very cheap storage for their chief products at the ports. This, where land is available, does not cost much, and it often changes the character of the trade to the advantage of the local community. In the absence of such accommodation the producer may be practically compelled to ship at once to London or elsewhere, and his goods have then to bear the heavy warehousing charges at such places, and he is to a large extent at the mercy of the buyers, who are generally not slow to fix a price among themselves. This practice, therefore, is less advantageous to the producer than a direct sale to a manufacturer's agent, and when storage presents no difficulties, this class of dealer is sure to spring up. These considerations are having their effect, and a great amount of produce which used to be shipped to London for sale is now sold on the spot and sent direct to the buyer.

## RAILWAY AND HARBOUR WORKS.

### Harbour Works.

DURING 1909 in the Sydney harbour an amount of timber was used which denuded at least 4,000 acres of the best forest country. Obviously this cannot go on much longer, especially as wooden piles are greatly affected by marine worms and climatic effects, and a great number of ports which have relied on timber will have to find a substitute. Many are trying reinforced concrete wharves and jetties, but there is some scepticism as to its efficiency. A timber pile is highly resilient and in any length in which it can be obtained will bear the bending movement of its own weight while being lifted. But a reinforced concrete pile of great length cannot be lifted without danger of fracture unless slung in two or three places, and is not so suitable as strong timber for resisting shocks. If any concrete is detached by shock, the steel bars may be exposed to the water and corroded. Thoroughly satisfactory methods have yet to be evolved for this purpose. No satisfactory method of bracing jetties laterally in this material has been devised, as braces cannot be moulded under water and if they are moulded on land they cannot at present be properly connected. As a retaining wall, the material is stable and can be adapted to indifferent foundations.

Wooden piles can be encased with Monier pipes filled in with concrete as a protection against the teredo. This gives a strong construction, but the extra cost is about £10 per pile.

---

### Suva Harbour Works.

A case where new harbour works are made necessary by the deterioration of timber occurs at Suva, where it is said that there is hardly a sound pile in the wharves, and a heavy jar from a large vessel might at any time be attended by serious consequences. The scheme in contemplation provides for a quay face, backed

by an extensive reclamation of about 2,000 feet, and of another quay on the south facing it of about 900 feet. One of the first steps in such a matter is to take careful borings so as to ascertain the depth and character of the mud. The harbour works at Singapore are suffering from the omission to carry out this important examination effectively, and it is obvious that if a scheme is drawn up with wrong assumptions on this matter it may be necessary to alter it largely, with serious complications if the work is being done by contract. It is further contemplated at Suva to arrange the works so that the depth alongside the quay, facing the harbour, shall be 28 feet at low water in the first instance. No doubt when the works are decided on, Australian contractors will be invited to send in tenders.

---

### Concrete.

Concrete materials are obtainable everywhere, but this very simplicity lends itself to abuse. One of the best aggregates for most purposes is ashes from locomotive boilers. Another factor, observes "Concrete," is the labour. "The cement may be good, the aggregate of a suitable nature and well graded, and the water clean, but if the materials are not thoroughly mixed and the water not suitably proportioned, the value of the concrete is seriously diminished. Machine mixing remedies this to a great extent, but for many building purposes mixing machines do not seem as yet to find much favour. The mixing of concrete is not a favourite occupation with workmen; it is laborious work which can be lessened if the materials are not wrist turned, but simply lifted in the shovel and deposited close at hand without being turned over."

Many "waterproofing compounds" have been put forward and have failed in practice. The theory of the requirements is set out as follows:—

1. The impermeability of concrete is simply a matter of density or closeness of texture. This is arrived at in no other way than by filling the pores of the concrete with finely divided insoluble material, which can be done either by properly grading the aggregate, or by the addition of powdered substances, of which slaked lime and China clay appear to be the two best, and most effective. Slaked lime has, however, a tendency to produce efflorescence on the surface; China clay has no such tendency.

2. Water repellants, such as greasy substances—lime soap, etc., have no real waterproofing properties. The waterproof compounds on the market are beneficial only so far as the slaked

lime (which forms 90 per cent. of their composition) acts as a pore filler. The 10 per cent., or thereabouts, of lime soap contained in these compounds is a defect rather than an advantage.

3. The action of sea water on concrete is probably entirely due to the permeability, and will be prevented if the concrete is made sufficiently dense and impervious.

4. The substances used as pore-fillers—especially clays—should be added to the cement or concrete in a *dry* state.

---

### American Locomotives.

The following remarks by Mr. G. G. Elliott, Pretoria, might well be studied by our makers.

“We have purchased two special types of locomotives in America, one because that particular type had been developed to a remarkable degree in America, and brought about a great departure in locomotive design, resulting in enormous economies. The idea did not, however, originate in that country. The United Kingdom, on the other hand, had done practically nothing in that line.

“Another reason was due to the enormous difference in cost, which we did not feel justified in incurring, in spite of the superior workmanship in the United Kingdom, compared with that of America.

“The other type was purchased to pit American design and workmanship against an engine of similar power and design built in the United Kingdom.

“Previous experience had proved that there is a great deal to be learnt from the Americans, who are an ingenious race, and we may surely not be accused of disloyalty to the Mother Country by patronizing the American markets occasionally; they are an English-speaking race and our cousins—in fact, English Colonials in many respects. Why not give them orders as well as scholarships?

“I feel convinced, too, that British manufacturers could offer lower prices were they not hampered by our marvellously expensive ideas of what we consider should be good workmanship. There seems to be a general tendency for the two countries to meet half-way, as to finish and workmanship.”

The American Malet locomotive has been designed to provide a greater hauling capacity without exceeding the axle load to which the permanent way is limited. In many cases that limit has been reached, and the only means of increasing the power is to adopt the articulated type of locomotive by which the weight is distributed over a greater length. The articulation of the joints, which is made necessary by the double carriage, is a

source of some trouble, but the greater power of the Malet locomotive is very substantial. It hauls about 50 per cent. more load than the simple locomotive, having eight driving wheels and the same weight per axle. Of 10 ton axle limit and 58½ tons adhesive weight, it cost about £5,000 in working order on the road. The American Locomotive Company alone have built a large number. The British firms have not yet acquired this experience, but they are building for South Africa and India.

---

### Harbour Cranes.

The question of suitable plant for harbours often arises and the following comparison may be useful.

For about £14,000 f.o.b. London, a crane on a pontoon can be supplied with a radius of 62 ft., and for loads up to 80 tons; the barge self-propelled to a speed of 6 knots an hour; the crane is fitted with an extended jib adapted for lighter loads. Such a crane has been supplied to the Auckland Harbour Board.

At nearly the same price sheers fitted to a pontoon can be provided for dealing with loads of 80 tons; the overhang from the perpendicular is 40 ft., pontoon similar to the above.

Fixed sheers on the pier for 80 ton loads, delivered and erected in a colony, would cost about £4,500; to this must be added the cost of any necessary foundations.

A floating plant is preferable in places when the wave disturbance is not so great as to affect the stability of the pontoon.

---

### Depreciation.

Depreciation of capital assets is a primary element of transportation expenses and should be shown in the statistics. This principle has been adopted on the South African Railways. Sir Thomas Price gives the following example of the working of the depreciation funds:—

“A locomotive is purchased at a cost of £5,000 on the opening of the Railway and is placed in traffic on 1st January, 1908. Its life is estimated at twenty years. Each year (in addition to the cost of all repairs) one-twentieth of its original cost is charged to working expenses under Locomotive Maintenance (depreciation) and credited to ‘Locomotive Renewals Fund.’ By the 31st December, 1927, this fund will show a credit balance of 20 times £250, £5,000. The original locomotive is now worn out, its scrap value being, say, £500. It is desired to purchase a new locomotive in place of the old one, and the following adjustment is made in the books:—

“An asset worth £5,000 has disappeared, so Capital Account is credited with £5,000 and Renewals Fund debited with that

amount. On the purchase of a new locomotive, say, for £6,000, Capital Account is debited with the cost.

“As regards the scrap value of the locomotive it is considered desirable for the present to credit Renewals Fund with the amount realised (less any cost of breaking up for sale), this amounts in fact to an additional contribution for depreciation.

“In case the locomotive were scrapped at the end of ten years (*i.e.*, 10 years before its estimated life expired) working expenditure would still be charged with depreciation on the engine for the remaining 10 years. If on the other hand, it lasted 50 years (*i.e.*, 30 years beyond its assumed life) no depreciation would be charged for it during the last 30 years.”

Sir Thomas Price goes on to say that this principle is extended to all assets of the railway which are liable to depreciation, the percentage set aside for depreciation being based on the estimated life. The following percentages have, in fact, been adopted on the Central South African Railways:—

Permanent Way, etc.	... ..	3½ per cent.
Brick and Stone Buildings	... ..	1½ „
Wood and Iron Buildings...	... ..	5 „
Rolling Stock	... ..	5 „

Labour charges are included in the Capital value, except in the case of Permanent Way.

### Australian Railway Extensions.

The Premier of New South Wales has stated that it is the intention of the Government to build pioneer railway lines in advance of settlement. This policy is justified if it is clear that the accommodation will result in a much greater value added to the land than is represented by the cost. He stated that between Wyalong, Hillston, and Lake Cudgellico there are one-and-a-quarter millions of acres of wheat land, held under lease. That land has been reported on as being suitable for settlement. The rainfall was sufficiently great to ensure a permanent settlement, and it would mean an expenditure of £3,000 a mile for 100 miles, a total of £300,000, to bring every acre of that one-and-a-quarter million acres of land in close proximity to market, under permanent settlement, and increase the value to the State to the extent of four-and-a-half millions of money, or from being valued at 10s. per acre to £3 per acre. The expenditure of little more than a quarter of a million of money would provide for a settlement by the making of a railway in that district, and give back to the State and the taxpayers the value to something like five times by the expenditure of that quarter of a million.

**Straits Settlements.**

Owing to difficulties which have arisen over the contract with the contractors, Sir John Aird and Sons, in respect of the Lagoon Wet Dock and Main Wharf Reconstruction, the Tanjong Pagar Dock Board have taken possession of the works, under a power reserved to them. The state of the work at the time will be recorded, and the rights of the parties will be a matter for settlement.

A very serious difficulty has also arisen over the Harbour Works. The scheme adopted was settled on the basis of certain borings, which, it is believed, cannot be relied on. A committee of experts has been appointed in London, to consider how the scheme can now be completed.

---

**Hong Kong.**

A boat shelter at Mongkoktsui is to be provided, the accommodation in the Boat Harbour in Causeway Bay being inadequate for the native craft which seek shelter in it. The tender of a Chinese contractor has been accepted, the amount being \$2,018,002.

---

**East Africa.**

Messrs. M. Samuel and Co. have entered into a further agreement, setting out detailed terms as to the proposed lease and contract, for the purposes of the construction of a railway and other works in the Protectorate, the option of which was given to them by an agreement of 1911, and the contract is under preparation. The Uganda Railway Administration has, under this agreement, to make such improvements in its main line, at an estimated maximum cost of £146,500, as may, in the opinion of the Governor, be necessary for carrying the quantity of 50,000 tons.

---

**Jinja-Kakindu.**

The preliminary traverse showed a length of 55 miles, an excess of eight over the estimate, due to broken country. To avoid heavy earthwork 10° curves have been used in a few cases with compensated grade, but on the whole the curvature is easy and gradients light.

An attempt to do the earthwork by piecemeal, with a minimum wage, proved a failure, the labourers being perfectly content with the minimum wage of Rs. 3 per month and rations, and openly doing as little as possible. It was thus decided to abolish the minimum wage. Some 4,000 natives are engaged and, as they are quite new to such work, the building of the line with native labour will be notable.

**Accra-Akwapim.**

In view of the unavoidable delay caused by the damage done by the floods of last year, the contract time for the completion of the railway has been extended to August 27th, 1911.

Good progress has been made with the survey of the proposed extension to Komfrodna. Due regard has been paid to the flood line of the Densu, to avoid the misfortunes experienced on the first works. Except for three trestle bridges there will be little heavy work.

---

**Freetown Harbour.**

The general situation has been arranged of a proposed export wharf with warehouse accommodation, and an examination is contemplated of the foreshore to determine its suitability for the work and the character of the berthage to be provided. The location of the branch railway will be governed by the result.

---

**Dredging the Niger.**

The dredger last year at the lowest water maintained a uniform depth of 5 feet in crossings between Lokoja and Baro, but the river was exceptionally high at the low water season.

---

**Nigerian Railways.**

It is contemplated that these shall be surveyed shortly by Major W. D. Waghorn, R.E., of the Indian service.

---

**Lagos Harbour Works.**

By the end of December the East Mole had been carried to a length of 5,571 feet, and the tonnage of stone deposited was 168,558. Of that length 1,503 feet are taken up by the extension of the mole northward from the wharf, which was decided on to protect the margin of the harbour from corrosive action. This mole will probably have advanced to such a point by the end of this year that it will be desirable to begin the West Mole. The train accommodation will be increased early next year to permit of a greater supply of stone from the quarry.

A start was made in January with Apapa Wharf, which is to be 345 feet long, with connection to the railway system near Ebute Metta.

The bar draught for steamers last year was from 13 to 16 feet.

The Customs Wharf will probably be completed in June.

---

**Trinidad.**

Three schemes for laying out the Siparia line from San Fernando have been under consideration. The original scheme

is the shortest, but it interferes with the Paradise Recreation Ground at San Fernando. The second route goes round the foot of the cliff and rises through a gap in the cliff beyond the recreation ground; this would necessitate a sea wall nearly 60 chs. in length to protect the line from damage by the waves, and the extra cost would be about £8,000. The third route continues round the coast from the point where the second commences to mount the cliff, at a lower level, in order to reduce the height of the walls, and to pass round the end of the hill near the Plague Hospital through the lower land bordering the Ciparo river, so as to join the San Fernando tramway further in advance. This line would be the longest, and the most expensive, as the wall though lower would be much longer. There is a fourth alternative, of passing from the wharf to a junction with the tramway at a point in the cutting between the Hospital and Harris Promenade, but the objection to this is the cutting would have to be sunk 21 feet lower, and this would involve risk to adjoining lands and in any case would be costly.

---

### Headlights.

It is rather curious that there is no method, in this country at any rate, of swinging the headlights to follow the movements of the bogie and so keep the beam of light on the road. There would be an obvious advantage in this. And apparently there is no demand for such an arrangement on our railways. On railways where obstruction and faults are more frequent the advantage would be greater. The headlight might be mounted in the frame with a spring weight arranged so that the tilting of the engine on a curve would swing it to point round the curve.

---

### Tropical Axle Oil.

Favourable reports have been received on this oil, supplied by the Vacuum Oil Company. The packing in one case in the axle box was quite clean after running nearly 3,000 miles, whereas other axle oils are often dirty and gummy and cause hot axles. Indian axle oil is also a fine oil but more expensive.

---

### Ash pans.

When a coal is used (such as Indian) which has a very high proportion of ash, the usual arrangement for damping the ash pan ashes is not effective enough. The small pipe from the gauge column cock may be too small, and the large pipe inside ash pan soon gets burned away. What is wanted is a branch from the overflow pipe of injector.

**Derailments.**

These are sometimes caused by excessive superelevation of the outer rail of the track on curves. The normal amount allowable should not be used until the road is in good order and the banks consolidated, or otherwise low places may be found which will increase the cant. If the side bearing springs are too stiff the vehicle is liable to derailment. The running can be improved by the use of the McCord Dampener on these springs.

---

**Decauville System.**

The Société Decauville, whose London office is in 40, Trinity Square, E.C., have, in addition to the many awards conferred on them, been awarded the Grand Prix at the Buenos Aires Exhibition, and have also been nominated Member of the Jury Hors Concours at the Universal Exhibition at Brussels.

---

**Till further notice.**

The following is a copy of a telegram despatched on the Lagos Government Railways:—"Head beater reports again that thunder took all the ballast away at 255½ miles. Driver to please look sharp or to wait at J.D. until further notice."

---

**A dam mistake.**

The following telegram was received at an African railway office on the 19th December last:—

*From Works Foreman. To District Superintendent.*

Now at Erin Dam.

After much scrutiny it was discovered that the wire should read: "No water in dam."

## MEDICAL NOTES.

THE practical importance of the study of tropical medicine has been brought home to the British public in an unpleasantly vivid manner by the recent discovery that plague among rats has established itself to a wide extent and on a firm footing in East Anglia. The small batch of human cases which occurred at Freston, in Suffolk, has fortunately not been followed by others. But it now appears that the infection among rats has become so widespread that there is little hope of stamping it out entirely. It has been conclusively proved that the agent of transmission is the rat-flea. There are different species of rats, the liability of which to infection differs, and there are also different species of fleas, some of which are more active as transmitters of the disease and more prone to attack human subjects than others. There is appreciably less risk of the transmission of the disease to human beings under the conditions prevailing in England, than under those characteristic of the Eastern communities where the plague has counted its most numerous victims. But it should be noted that the Freston cases were all of the pneumonic type, which, unlike the bubonic, is directly transmissible from one human being to another, and which has resulted in a terribly high rate of mortality in the present Manchurian epidemic. Striking as the results of research into the causation of plague have been, more knowledge on the subject is urgently required, and can only be obtained by organized continuous effort and adequate funds. The outbreak in Suffolk affords no ground for exaggerated alarm, and the many months of immunity from further human infection are distinctly encouraging; but it should serve as an object-lesson to bring home to everyone the vital importance of scientific research in this particular field as the sole weapon of defence against one of the most terrible scourges which humanity has known.

The Sleeping Sickness Bureau has issued Bulletins No. 22 (completing Volume II.), 23 and 24. In addition to special articles dealing with recent research into trypanosomiasis, each number contains the latest news relating to the disease from the various parts of Africa affected by it. We have also received from the Liverpool School of Tropical Medicine, Vol. IV., No. 3, of "Annals of Tropical Medicine and Parasitology," the principal article in which, by Major Ross and Doctor David Thomson, deals with "Some Enumerative Studies on Malarial Fever."

---

The Report of the Advisory Committee for the Tropical Diseases Research Fund for 1910 has been published (Cd. 5514, price 1s. 1d.). Expenditure for the year amounted to £5,258, against a revenue of £3,245, necessitating a heavy draft on the accumulated balance, and the Committee emphasize the need for further funds. Appendices to the Report contain accounts of anti-malarial measures in the Colonies, and of research work at London and Cambridge Universities, the London and Liverpool Schools of Tropical Medicine, and various Colonial Laboratories. There are also included a report on beri-beri from Siam, and an account by Dr. Breinl, Director of the Australian Institute of Tropical Medicine, Townsville, of the results of his journey to the northern part of Queensland.

---

A "Summary of Facts regarding Malaria, suitable for Public Instruction," which has been taken from Professor Ross's work on "The Prevention of Malaria," has been published in pamphlet form by Mr. John Murray. Price Twopence. First issued in December last, it has already had to be reprinted, and it is to be hoped that it will be widely circulated among residents in, and visitors to, malaria-infected countries.

---

### Blood Stains.

A case has come before us in which a Colonial police were exercised by this cheerful subject. It is sometimes helpful in criminal cases if it can be decided whether a blood-stain is recent or old, and though scientific examination does not enable a definite answer to be given it gives a rough estimate. After a blood-stain has become dried, and is about a week old, no definite change occurs for some months. The spectra then becomes altered owing to the hæmoglobin changing to met-hæmoglobin, then to hæmatin, then to hæmatoporphyrin. There is no definite rate of

change as it varies according to the atmospheric conditions, but a rough idea is given by the amount of shrinkage of the blood corpuscles shown by microscopical examination.

---

### Entomological Research.

In connection with the gift of £1,000 per annum for three years made by Mr. Andrew Carnegie to the Entomological Research Committee (Tropical Africa), two students have been selected to proceed to the United States to take a course of instruction in economic entomology.

## COLONIAL STAMPS.

It is improbable that any Colonial stamps showing the head of H.M. King George will be ready until the close of the year. Since the issue of our January number a way of combining the advantages of the two forms of General Keyplate there referred to has been thought of, and if the design proves to be a success it will be possible to secure the fine appearance of the stamp of the Nyasaland Protectorate type without the disadvantage of a separate set of duty indicating plates for each of the purposes to which the stamps may be put. The great obstacle to the alteration of the Keyplate for the better has been that many Colonies have overprint plates to fit it, but it is hoped that this difficulty may be got over by the manufacturers agreeing to supply overprint or border plates free of charge to replace those which would be rendered useless. The use of the General Keyplate will probably be extended by the fact that the price of printing stamps in two operations has been very greatly reduced, and even comparatively small numbers of stamps can be printed by this system in two colours at a very much cheaper rate than a larger number of stamps in one colour by the copper plate process.

It may be useful at this point to sum up the chief advantages of the copper plate and surface printing processes, a matter into which we went at some length in the first number of this journal.

The advantages of surface printed stamps are :—

- (1) The cost of printing is much less as the process is much more rapid.
- (2) Two colours can be employed at a price not very much higher than one.
- (3) A much more fugitive ink can be employed, and, where necessary, doubly fugitive ink ; the removal of cancellation without affecting the colour is thus rendered much more difficult.
- (4) The perforation, so far as this is of importance, is much more accurate, as the paper is not wetted before printing with consequent unequal shrinkage on drying.

(5) A General Keyplate is available for use by any Colony, without appreciable charge, which will enable "Postage," "Revenue" or unified stamps to be produced at will.

The advantages of the copper plate system are:—

(1) It admits of a better finished or more elaborate design; and of (2) a more varied series of stamps, as the cost of dies is so much less than those required by the other process that separate ones can be used for each value.

As indicated under the head of surface printing the cost of printing in two colours by the copper plate process is very high. The reason for this is that the paper has to be wetted for each printing and the shrinkage has to be allowed for; the time occupied by drying, etc., is considerable, and the gumming and milling of the sheets have to be done after printing, and not in large quantities in anticipation of the order for the stamps.

---

It does not appear to be generally known that the stamps issued by the groups of Islands in the Western Pacific are not obtainable from Fiji. In order to save trouble to the authorities at Suva, and disappointment to applicants for the new stamps, we append a list of the addresses to which applications should be sent, but this notice must not be taken as a guarantee that the stocks in hand are at any moment sufficient to meet all applications.

NEW HEBRIDES (Condominium).—English values, The Postmaster, Vila, New Hebrides. French values, Agence Comptable des timbres poste Coloniaux, 36 rue Vaneau, Paris.

BRITISH SOLOMON ISLANDS PROTECTORATE.—The Postmaster, Tulagi, Solomon Islands.

TONGA.—The Postmaster, Nukualofa, Tonga.

GILBERT AND ELLICE ISLANDS PROTECTORATE.—The Postmaster, Ocean Island, Gilbert and Ellice Islands.

---

BERMUDA.—½d. stamps of the new design have been supplied.

HONG KONG.—20 cents, 30 cents, and 50 cents stamps have been recently despatched in the new colours.

NEW HEBRIDES (Condominium).—In addition to the French values given in our note in the January number, two others have also been issued, *i.e.*, 30 and 40 centimes, in the colours appropriated to 3d. and 4d. stamps respectively. The whole of both series is printed by the copper plate process and on ordinary paper.

ST. LUCIA.—5s. stamps from the old King Edward's Head Keyplate have been supplied for the first time in the new colours.

SIERRA LEONE.—£1 stamps have been supplied for the first time in the new colours.

SOMALILAND PROTECTORATE.—The note under this head in our last issue should have stated that the paper was, for the first time, both surfaced and multiple watermarked.

STRAITS SETTLEMENTS.—4 cents stamps are now being supplied in a rather brighter purple. The colour has been changed in order to make it easier to distinguish this stamp from the 21 cents stamp.

TURKS ISLAND.—The colour of the  $\frac{1}{4}$ d. stamps of the "Turk's Head" design being considered unsatisfactory, the second consignment, which has recently been despatched, has been printed in a brighter red.

---

"The Cayman Islands: their Stamps and Post Office," by D. B. Armstrong, is a truly exhaustive treatment of its subject, from the external appearance of the little Post Office to the time tables of the local clearings and deliveries. The intervening matter must, we imagine, be the fruits of enormous research, every minute variety seeming to be described and, in most cases, accounted for and fully illustrated.

## RECENT TRANSFERS AND PROMOTIONS MADE BY THE SECRETARY OF STATE.

- Mr. A. M. COLL, K.C. (Attorney-General, Gibraltar), Chief Justice, Jamaica.
- Mr. W. D. BARNES (Resident of Pahang, Federated Malay States), Colonial Secretary, Hong Kong.
- Major J. E. CLAUSON, C.M.G. (Chief Secretary to Government, Cyprus), Chief Secretary to Government, Malta.
- Mr. H. C. GOLLAN (Chief Justice, Bermuda), Attorney-General, Trinidad.
- Mr. B. H. T. FRERE (Police Magistrate and Coroner, Gibraltar), Attorney-General, Gibraltar.
- Mr. J. E. GREEN (Solicitor-General, Southern Nigeria), Puisne Judge, Southern Nigeria.
- Captain C. W. J. ORR, D.S.O. (First Class Resident, Northern Nigeria), Chief Secretary to Government, Cyprus.
- Mr. E. CARLYON ELIOT (Provincial Commissioner, Gold Coast), Warden and Magistrate, Tobago.
- Dr. G. J. RUTHERFORD (Provincial Medical Officer, Gold Coast), Assistant Principal Civil Medical Officer, Ceylon.
- Mr. C. V. A. ESPEUT (Executive Engineer, Public Works Department, East Africa Protectorate), Chief Engineer, Uganda.
- Mr. F. H. LONGHURST (Executive Engineer, Public Works Department, Northern Nigeria), Deputy Director of Public Works, Gold Coast.

- Lieutenant C. S. BURNETT (late Lieutenant, 2nd Battalion, Southern Nigeria Regiment, West African Frontier Force), Assistant Resident, Northern Nigeria.
- Lieutenant A. W. NORRIS (late Lieutenant, 1st Battalion, Gold Coast Regiment, West African Frontier Force), Assistant District Commissioner, Gold Coast.
- Mr. H. E. M. CAMPBELL (5th Class Clerk, Post Office, British Guiana), Inspector, Post and Telegraph Department, Gold Coast.
- Mr. H. E. FENWICK (District Officer, Public Works Department, Trinidad), Engineer of Roads, Gold Coast.
- Mr. F. le C. BELMAR (Sub-Collector of Revenue, St. Lucia), Junior Assistant Treasurer, Northern Nigeria.
- Mr. W. CUNNINGHAM (Second Assistant Surveyor, British Honduras), First Class Officer, Department of Lands and Mines, British Guiana.
- Mr. C. F. BRISTOW (retrenched from the South African Constabulary), Assistant Inspector of Police, Uganda.

## OFFICIALS ON LEAVE OF ABSENCE IN THIS COUNTRY WITH DATE OF EXPIRATION OF LEAVE.

—

This List is compiled from the Leave Certificates sent to the Crown Agents for the Colonies. The Editors will be glad to receive notice of any other cases of Colonial Officials on Long Leave.

ALBION PATENT MAGNETS.  
ALBION PATENT CARBURETTOR.  
ALBION PATENT CHAIN CASE.  
ALBION PATENT LUBRICATOR.  
MURRAY PATENT GOVERNOR.

**A**LBION Motor Vehicles are manufactured throughout at our works under our own patents. We do *not* adopt the dangerous practice of purchasing the principal parts complete from different manufacturing firms, and then assembling them only. The selection of the best material is therefore always under our direct control, thus ensuring that regularity and reliability in the complete vehicle which otherwise is difficult to obtain.

**ALBION MOTOR CAR CO., Ltd., Scotstoun, GLASGOW.**

**London Depot: 21-22, Upper Rathbone Place, W.**

Codes: A.B.C., 5th Edition,  
and Leibers.

Telegrams: "Automobile, Glasgow."  
"Karalbo, London."

# R.M.S.P.

**THE ROYAL MAIL  
STEAM PACKET COMPANY.**  
(ROYAL CHARTER, DATED 1839.)

## The Line for Luxurious Travel.

From  
SOUTHAMPTON  
& CHERBOURG  
to  
**WEST INDIES**

(PACIFIC),

**NEW YORK,**  
via The Azores.

**BRAZIL**

&

**RIVER PLATE,**  
via Spain,  
Portugal,  
& Madeira.

From LONDON to  
**MOROCCO,**  
Canary Islands,  
**MADEIRA.**  
23 DAYS, from  
£21.

From GRIMSBY &  
LEITH to  
**NORWAY**  
Fjords, North  
Cape &  
Christiana,  
July & August  
from  
£1 A DAY.

For further particulars apply for Illustrated Handbooks "A.J."

London: 18, Moorgate Street, E.C. & 32, Cockspur Street, S.W.

# BENSON'S

"THE VILLA" Solid Oak Case, with Lift-out Trays,  
containing 110 pieces of "Empire" Plate and  
Sheffield Cutlery.

A Service for 12 persons **£12 10s. to £21.**  
(Others £3 to £100.)

## "EMPIRE" & STERLING SILVER PLATE

SPOONS, FORKS, TABLE CUTLERY,  
AND OTHER HOUSEHOLD WARE.

"EMPIRE" PLATE is trebly  
plated on pure Nickel Silver. The  
patterns are reproductions from fine  
old Silver models, and have all the  
beauty of line and form of the Silver  
of 150 years ago; apart from the Hall  
Mark no difference is visible.

At the 1862 Exhibition,  
"Empire" Plate was awarded Prize  
Medals for Excellence of Manufacture,  
and it still retains that pre-eminence  
for which it was noted fifty years ago,  
whilst the prices are, quality con-  
sidered, strictly moderate, either for  
Cash, or on "The Times" System  
of Monthly Payments.

PRICE  
LISTS  
FREE.

No. 1, of Watches, Clocks and  
Jewellery.

No. 2, of Clocks, "Empire" Plate,  
Cutlery, and Silver Articles,  
for Presents.

Mention "Colonial Office Journal."

**62 & 64, LUDGATE HILL, E.C.**

# MERRYWEATHERS'

Patent Improved

## Vacuum Cesspool Exhauster

Merryweathers' Exhauster in Use.

Arranged for  
Hand, Horse  
or  
Motor Draught.

### **ADVANTAGES :—Absolutely Sanitary.**

Can be employed in daytime without causing a nuisance. The pump creates a vacuum in the cylinder, the suction pipe is lowered into the cesspool and the contents immediately transferred to the cylinder without passing through the pump. The gases exhausted are burnt in the stove.

*Extract from Medical Officer's Report :—*

“Very pleased with its efficient and simple method of working, and believe that it will be adopted in other urban districts where extended systems of sewerage are not able to be carried out.”

Write for Illustrated Lists 690 M.

# MERRYWEATHER & SONS,

Greenwich Road, S.E., LONDON.

*Ask for new Catalogue of Hose for  
Flushing and Watering Purposes.*

# "ETERNIT" (ASBESTOS-CEMENT) SLATES & TILES.

Weight per yard of finished roof, 22 lbs.

**Tensile Strength: 5,781 lbs.    Crushing Force: 8,281 lbs.**  
per Square Inch.

(Hatschek's Original Patent.)

ON THE ADMIRALTY AND WAR OFFICE LISTS.

Smooth on both sides.  
66½ lighter weight per Square than Bangor  
Slates.  
30 per cent. greater mechanical and tensile  
strength.  
Non-Conducting.    |    Impervious to sun-  
Non-Combustible.    |    heat, frost and rain.

### SPECIALITY:

"ETERNIT" Terra-Cotta Tiles which  
neither break nor crumble, and at half the  
cost of Red Clay Tiles and double the  
strength. Stronger than any other Asbestos  
Slate.

## "ETERNIT" (Asbestos-Cement) SHEET FOR WALLS AND CEILINGS.

Fireproof; easily and rapidly fixed with carpenters' tools. Does not rot or shrink, and supersedes lath,  
plaster and matching. Size 8 ft. by 4 ft.—4 ft. by 4 ft. by ½ in. thick and upwards. Manufactured  
under the British Patent Rights.

*Sole Concessionaries and Contractors to H.M. Government:*

# HOMAN'S Solar Chronometers and Solar Clocks.

*(Fully protected by Patents.)*

**THE ONLY TIMEPIECE OF  
ITS KIND IN THE WORLD.**

All the instruments are supplied with bowls 12 inches in diameter, and engraved brass scales. They are **complete in every respect**, so that they can be set up by anyone.

The price includes carriage to any part of the world.

Turned Gunmetal Solar Chronometer, Ornamental Gunmetal Base	£	7	s.	10	d
The same in Sheet Copper, Plain Base, as in illustration	-	-	-	2	10 0
The same in Cast Iron, Ornamental Base	-	-	-	2	10 0
The same in Coppered Steel, Plain Base, as in illustration	-	-	-	1	10 0

(Although every precaution is taken to make the instrument of coppered steel durable, it is safer to order one of the others when it will be continually exposed to the weather.)

**All the above instruments show Standard Mean Time correctly and accurately.**

The **Solar Clocks** are of the same price and the same finish as the above. They **show Standard Solar Time**. A table showing how much this is faster or slower than Mean Time is attached to each instrument.

The **Solar Clocks** have no movable parts, and they are therefore stronger and preferable to the **Solar Chronometers** in positions where they are liable to be tampered with.

Plate glass, copper framed covers with letter locks for any of the above instruments are supplied for 10s. each extra.

The instruments are intended to be fixed either on a horizontal surface, such as a pedestal, or vertically on a wall. When not otherwise specified they will be supplied for attaching to a horizontal surface.

A **Solar Chronometer**, or a **Solar Clock** in Cast Iron, Bowl 30 inches in diameter, with engraved Brass Scales, can be supplied for £10, carriage paid to nearest port. It is specially designed as a **Standard Timepiece for villages and small towns**. It can be set up **without skilled labour**, and forms an **invaluable Standard Clock**, always giving the right time to the nearest minute, whenever the sun shines, between 6 a.m. and 6 p.m.

**HOMAN'S SOLAR CHRONOMETERS, 20, Renfrew St., Glasgow, Scotland**

## JAMAICA AND BERMUDA.

---

THE GAMBIA, SIERRA LEONE, GOLD COAST  
AND  
SOUTHERN AND NORTHERN NIGERIA (INCLUDING LAGOS).

---

### REGULAR WEEKLY EXPRESS SERVICES

(CARRYING HIS MAJESTY'S MAILS)

are maintained out and home between Liverpool and Sierra Leone, Gold Coast (Axim, Sekondi, Accra), Lagos, Bonny and Calabar (fortnightly to the Gambia), and all the principal West African ports by the—

**British and African Steam Navigation Co., Ltd., and African Steamship Co.**

### EXCELLENT ACCOMMODATION

with all Modern Conveniences, Hot and Cold Baths, Electric Light and Bells, is provided for passengers. The express service Steamers are also fitted with refrigerating chambers, ensuring a constant supply of fresh meat, vegetables, &c., all through the voyage.

---

### The Imperial Direct West India Mail Service Co., Ltd.

maintain a regular fortnightly service (under Contract with His Majesty's Government) between Avonmouth, Bristol and Jamaica (Kingston).

To and from Bermuda there is also a regular service every six weeks by the R.M.S. "Port Kingston."

These Steamers have been specially built for the service and have magnificent accommodation for First and Second-Class Passengers at moderate rates.

---

THE LARGE MODERN HOTEL "CONSTANT SPRING" provides excellent accommodation at reasonable rates.

The Island of Jamaica possesses great natural beauty, and its warm healthy climate is recommended by the medical faculty. Polo-playing, Yachting, Golf, Tennis, Riding and Driving, are particularly good, and there is excellent Shooting and Fishing.

**A VALUABLE MEDIUM FOR  
DEVELOPING BUSINESS**

between the United Kingdom and India is the

**“ HOME AND COLONIAL MAIL.”**  
(WEEKLY)

For INDIA, CHINA, JAPAN, and the COLONIES.

ESTABLISHED over twenty-five years ago, this Journal occupies a unique position as a Commercial Newspaper, representative of the important planting and mercantile interests of India, Ceylon and the Far East.

It is filed in the offices of Tea Garden and Produce Agents in London and Calcutta, and is read by all interested in commerce, planting, and produce everywhere. Complete information is given about Tea, Rubber, and other produce, together with the machinery used.

Lists of Tea and Rubber Companies registered in London, Reports of Meetings and statistical information about produce, etc., appear every week.

Annual Subscription post free to India and the Far East, £1 7s.

# BENSON'S

## "EMPIRE" & STERLING SILVER PLATE

SPOONS, FORKS, TABLE CUTLERY, AND OTHER HOUSEHOLD WARE.

"EMPIRE" PLATE is treble plated on pure Nickel Silver. The patterns are reproductions from fine old Silver models, and have all the beauty of line and form of the Silver of 150 years ago; apart from the Hall Mark no difference is visible.

At the 1862 Exhibition, "Empire" Plate was awarded Prize Medals for Excellence of Manufacture, and it still retains that pre-eminence for which it was noted fifty years ago, whilst the prices are, quality considered, strictly moderate, either for Cash, or on "The Times" System of Monthly Payments.

"THE VILLA" Solid Oak Case, with Lift-out Trays, containing 110 pieces of "Empire" Plate and Sheffield Cutlery.

A Service for 12 persons £12 10s. to £21.  
(Others £3 to £100.)

PRICE  
LISTS  
FREE.

No. 1, of Watches, Chains and Jewellery.  
No. 2, of Clocks, "Empire" Plate, Cutlery, and Silver Articles for Presents.

Mention "Colonial Office Journal."

# MERRYWEATHERS'

Patent Improved

## Vacuum Cesspool Exhauster

Merryweathers' Exhauster in Use.

Arranged for  
Hand, Horse  
or  
Motor Draught.

### **ADVANTAGES :—*Absolutely Sanitary.***

Can be employed in daytime without causing a nuisance. The pump creates a vacuum in the cylinder, the suction pipe is lowered into the cesspool and the contents immediately transferred to the cylinder without passing through the pump. The gases exhausted are burnt in the stove.

*Extract from Medical Officer's Report :—*

“Very pleased with its efficient and simple method of working, and believe that it will be adopted in other urban districts where extended systems of sewerage are not able to be carried out.”

## If Concrete Beams Were Transparent

and you could see the internal strains on concrete and steel, you would not consider using a loose or semi-loose stirrup system of reinforcement. You would see clearly how the loose stirrups tend to slip along the main bar as they strive to transfer their shearing stresses into the main tension member.

You would also see many of the stirrups out of place, some omitted entirely, and the reinforcement not at all in the place called for in the designs.

You would then insist on the *rigid connection of Shear Members* and not depend on the questionable adhesion of concrete which may be lacking as the result of a severe fire, of the shock of moving loads, or of careless or unintelligent labour.

You would recognize the economy of a system which combines many separate bars in a complete unit and does away with expensive assembling on site.

Why not specify KAHN TRUSSED BARS outright, or wait until you have received our Scheme before letting your contract?

Write for our Handbook or for catalogues, specifications, and any information you need.

# NO DISINFECTANT

is so EMINENTLY SUITABLE for the use of

## THE TROPICAL SANITARIAN

as

**"SANITAS-OKOL"**  
(Emulsion).

"SANITAS-OKOL" has been largely adopted by Government Departments and Public Health Authorities throughout the Empire, and has been found the most suitable Disinfectant in every way. It can be used in all proportions and with all qualities of water, salt or fresh.

It has a high Guaranteed efficiency as a germicide, is non-toxic and non-corrosive, and retains, to a very marked extent, its efficiency in the presence of organic matter.

It is suited equally well for use by private persons as by Public Officials.

In addition to its germicidal character, it has marked value as a larvæcide and insecticide for use as a preventive measure against insect pests such as Flies, Fleas, Mosquitoes, and other disease carriers.

Special quotations given to Colonial Officials for large quantities.
